1 – OVERVIEW

Bezop is a decentralized peer-to-peer ecommerce order management and processing system, an autonomous buyer-seller protection service, and a simple value added tax (VAT) collection system - all powered by smart contracts and built on a decentralized blockchain network. Bezop aims to provide a complete open source solution for running a successful ecommerce business online. Merchants can participate by selling products and services on their self-hosted ecommerce stores (the Bezop Decentralized Order Management, or Bezop DOM) and broadcast orders to the network.

The Bezop market runs on a blockchain with a native ERC-20 protocol token (also called a "Bezop"), which miners earn on the ethereum blockchain by proof of work. Clients spend Bezops when purchasing goods and services in the Bezop DOM and in other integrated sites that offer services and accept payments in Bezops. Conversely, one can earn Bezops by selling goods and services and/or by simply receiving Bezops via a wallet-to-wallet transfer. In the future, a Bezop Network will emerge where miners compete to mine blocks with sizable rewards. Before then, Bezop mining power will be proportional to active orders on the network, which means that the value of Bezop mining will not be limited to maintaining blockchain consensus. This creates a powerful incentive for miners to fulfill as many orders as they can. The ERC-20 protocol weaves these amassed resources into a self-healing blockchain network that anybody in the world can rely on. Strong buyer protection techniques built in smart contracts reinforces the robustness of the network. Orders are encrypted end-to-end through the protocol's secure order management portal. Miners do not have access to decryption keys. Bezop works as an incentive layer on top of blockchain and computes a proof-of-order for any transaction, which makes Bezop particularly effective for decentralizing payments, building and running distributed ecommerce portals, and implementing smart contracts.

1.1 Elementary Components

The Bezop protocol builds upon six novel components:

I. Decentralized Order Management (DOM): open source order management and fulfilment portal

II. Bezop Network: A smart-contract friendly blockchain network

III. Proof of Order: A brief overview on the various proofs - the details of these novel proofs-of-order are presented in Section 3 (Crowd Token Program Details) of this paper.

- A. Proof-of-Tax : a VAT transaction holds data, pointing to the main transaction - x must be computed for correctness by taking the hash of $\gamma.\Phi$.
- Tax Data: $\{\alpha|\text{obj}: \text{val}, \gamma|\text{str}: \text{val}, \delta|\text{float}: \text{val}, \epsilon:\text{bool}:\text{val}, x|\text{str}:\text{val}\}$
- B. Proof-of-Transaction: Serves a receipt and shows all information about the product or service purchased.
- Transactional Data: $\{\alpha|\text{obj}: \text{val} \beta |\text{str}: \text{val}, \gamma_1|\text{str}: \text{val}, \delta_1|\text{float}: \text{val}, \epsilon:\text{bool}: \text{val}, \text{tid}|\text{str}: \text{val}\}$

IV. Proof-of-Delivery: Proofs that a product or service was delivered

V. Bezop Smart Contracts and Promises: Smart contracts will enable a completely safe and trustless ecommerce solution working flawlessly together on the proof-of-order protocol and ensuring buyer protection via the blockchain.

VI. Proof-of-Work (POW): Bezop will be based on the same POW system as Ethereum, which will further be upgraded to a full 'Proof-of-Order' where miners do not need to spend computation to mine blocks, but instead confirm orders on the network.

1.2 Ethereum Network and ERC-20 Token

Running on a custom-built Ethereum blockchain, Bezop is an enormously powerful and transparent global infrastructure that can move value around while simultaneously representing the ownership of property. This allows us to create Bezop markets, store registries of transactions, deliveries, order status, and taxes, and move funds in accordance with instructions given long in the past (such as a will or a futures contract). Such capabilities can potentially foster many more future inventions, all without a middleman or counterparty risk. The power of smart contract, Ethereum network, and Ethereum's decentralized platforms ensure that transactions that commonly occur in ecommerce can be executed in Bezop without any possibility of downtime, censorship, fraud or third party interference.

Correctness of an Algorithm

Correctness of an algorithm is asserted when it is said that the algorithm is correct with respect to a specification. Functional correctness refers to the input-output behaviour of the algorithm (i.e., for each input it produces the expected output).

A distinction is made between total correctness, which additionally requires that the algorithm terminates, and partial correctness, which simply accept an answer as a correct one as long as it is returned. Since there is no general solution to the halting problem, a total correctness assertion may lie much deeper.

A termination proof is a type of mathematical proof that plays a critical role in formal verification because total correctness of an algorithm depends on termination. For example, when successively searching through integers 1, 2, 3, ... for certain phenomenon, say, an odd perfect number, it is easy to write a partially correct program (using long division by two to check if n is perfect or not). However, no currently known number theory can support a statement that the program is totally correct.

```
curl_easy_setopt(conn, CURLOPT_ERRORBUFFER, errorBuffer);
if (rc != CURLE_OK)
    fprintf(stderr, "Failed to set error buffer [%d]\n", rc);
return false;

curl_easy_setopt(conn, CURLOPT_URL, url);
if (rc != CURLE_OK)
    fprintf(stderr, "Failed to set URL [%s]\n", errorBuffer);
return false;

curl_easy_setopt(conn, CURLOPT_FOLLOWLOCATION, 1);
if (rc != CURLE_OK)
    fprintf(stderr, "Failed to set redirect option [%s]\n", errorBuffer);
return false;
```

```
(void) attributes;
}

// libxml end element callback function
//
static void EndElement(void *voidContext, const xmlChar *name)
{
    Context *context = (Context *)voidContext;
    if (COMPARE((char *)name, "TITLE"))
        context->addTitle = false;
}

//
// Text handling helper function
//
static void handleCharacters(Context *context, const xmlChar *chars, int length)
{
    if (context->addTitle)
        context->title.append((char *)chars, length);
}

// libcurl CURLOPT_DATA callback function
```

1.3 Market Opportunity and Business Model

According to Boston Consulting Group, the payment industry is about to experience a significant shift towards mobile payments:

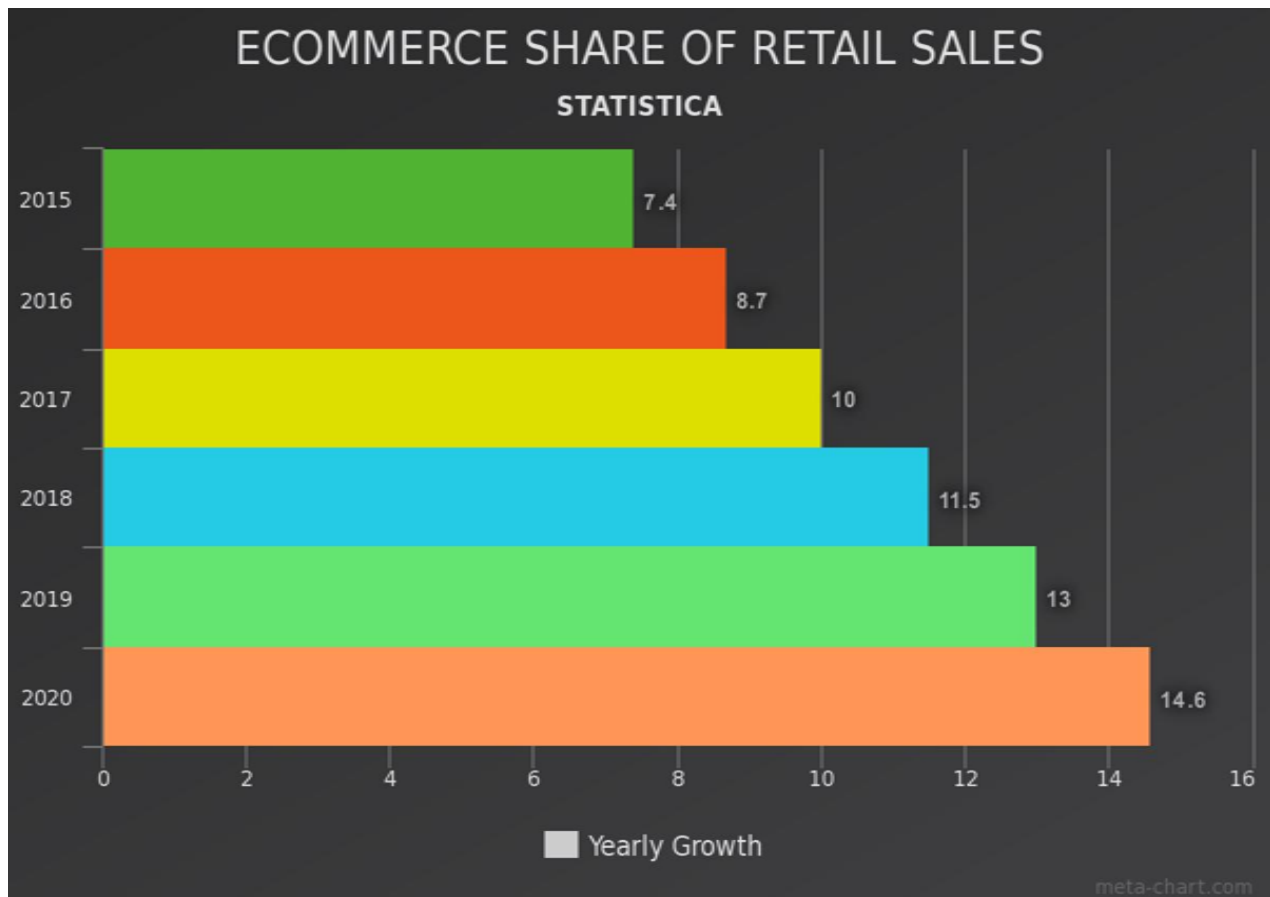

- Mobile payment volume was USD 8.6 billion in the United States. It is expected to increase tenfold by 2021 to reach USD 274 billion.
- Mobile share of total ecommerce is expected to increase to 48.5% by 2020. It was 23.6% in 2015.
- Merchant mobile payment acceptance network is expected to grow tenfold by 2020.

1.3.1 Explosive growth of ecommerce

According to Statista, worldwide ecommerce sales in 2014 were USD 1.33 trillion and are projected to increase to USD 4.06 trillion by 2020. The growth is perfectly illustrated by the number of shops created on the Shopify platform. The platform hosted 84,000 shops in 2013, 144,000 in 2014, 243,000 in 2015, and almost 378,000 in 2016 - a growth of 450% over 3 years.

Globally, ecommerce is also gaining share in total retail sales. It is expected to increase from 7.4% in 2015 to 14.6% in 2020.

Furthermore, according to Statista, the number of people buying goods or services online will increase from 1.46 billion in 2015 to over 2 billion in 2020.

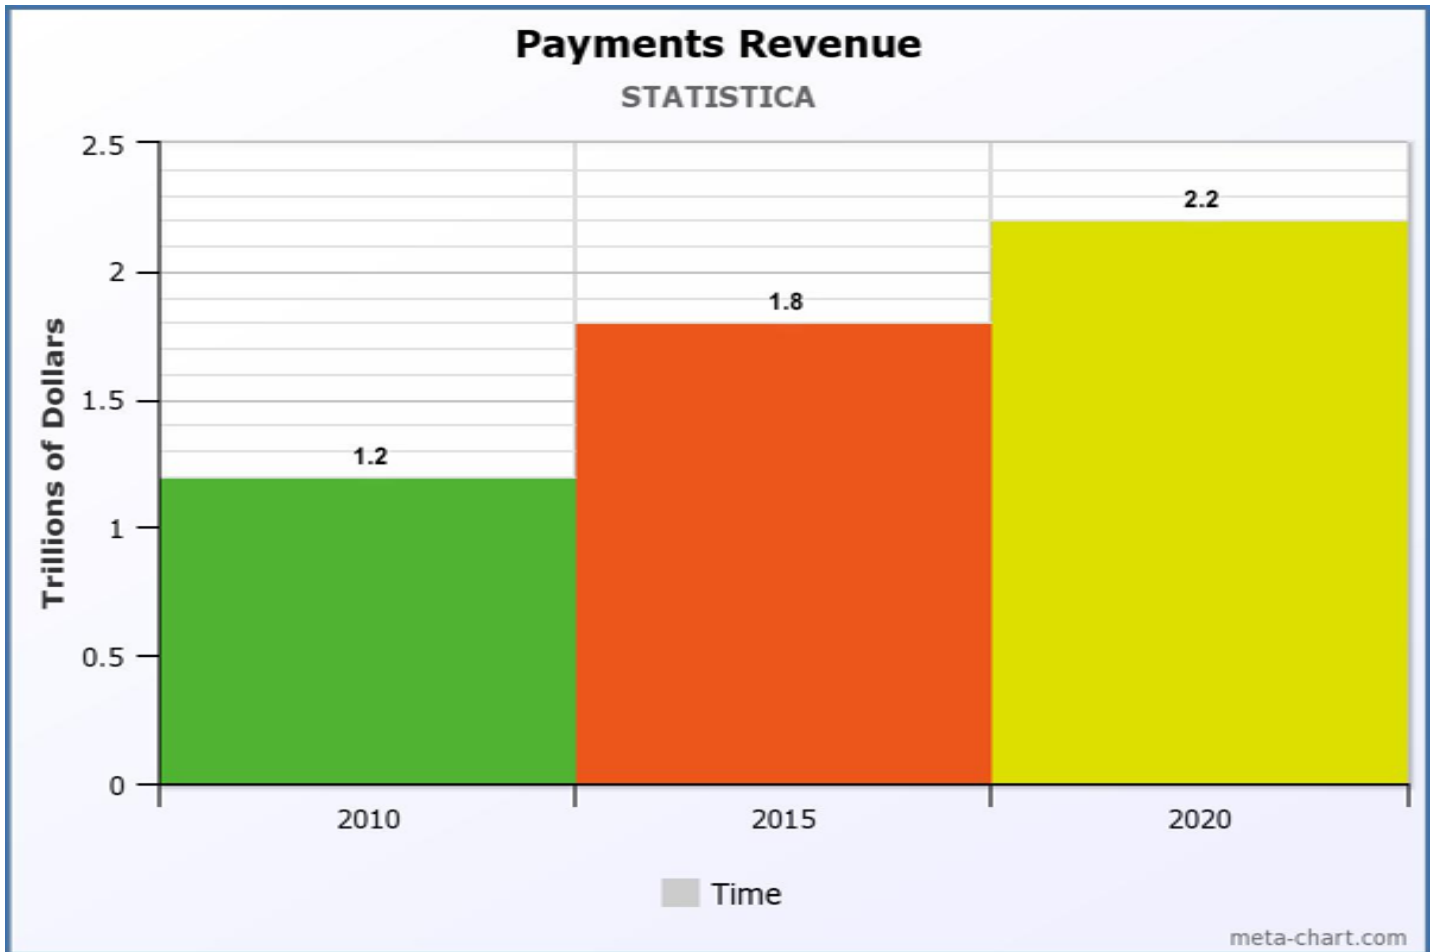

1.3.2 Transaction volume and global payment revenues

The payments industry is enormous. The total value of global retail payment transactions was estimated at USD 16 trillion in 2015. This is estimated to increase to USD 21 trillion by 2020. The estimates include consumer-to-merchant transactions across retail verticals such as food and grocery, apparel, consumer durables, etc. Digital payments contributed USD 1.26 trillion, or 8% of the global retail payments in 2015, and is projected to increase to USD 6.3 trillion, or 18-24%, by 2020.

The global payments revenue market size is approximately USD 2 trillion and steadily rising. In most cases, global payments are the payment revenues that include direct and indirect revenues generated by non-cash payment services (excluding interbank transfers). Simply speaking, it is the total revenues collected by financial services companies around the globe.

As shown in the graph below, the global payment revenues should reach USD 2.2 trillion in just a few years.

1.3.3 Business model

Bezop provides an open source web software system where merchants can sell their goods and services. Additionally, Bezop provides a network that processes cryptographic tokens. These tokens are the accepted form of payment (Bezop coin).

Bezop's smart contracts will autonomously manage the order's state. In the event of a dispute, a smart contract can assign a human agent to make the final decision.

Bezop charges a 1.4% processing fee from merchants. Of that, 1% will be used to maintain the services, support marketing, and cover payrolls.

1.4 1-Click Amazon Web Services Cloud Miner Setup

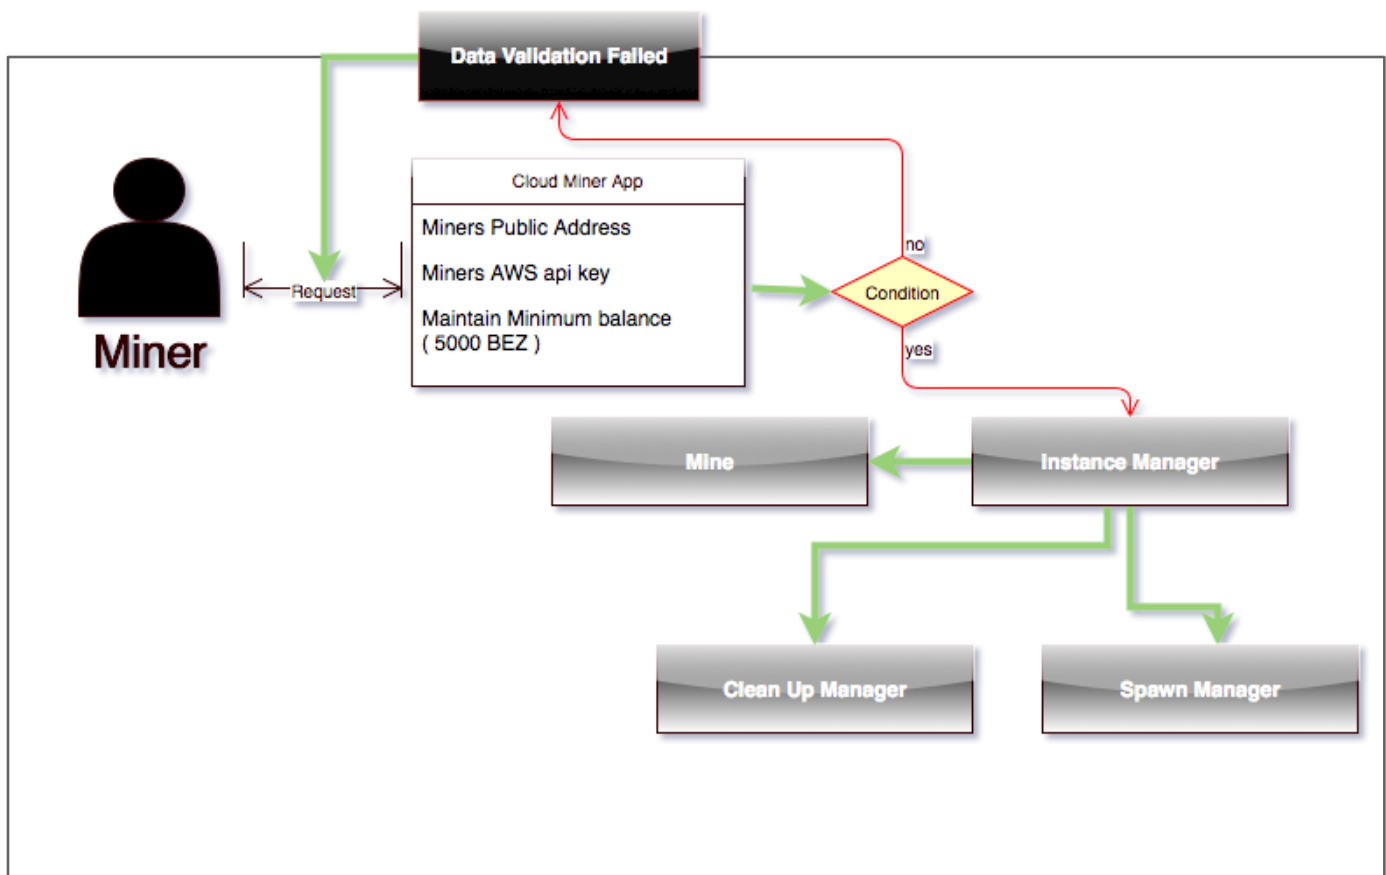

The Bezop network will allow miners to profit by mining on the cloud utilizing Amazon Graphics Processing Unit (GPU) instances.

A miner must provide a working Amazon API key and a Bezop standard address with a minimum of 5,000 Bezops.

The complexity of configuring this miner will remain hidden as the network will take full control through the API.

- The network will be in charge of spawning new instances.
- The network will terminate low performing and unresponsive instances.
- The network can continue mining even when the miner's devices are off.

The diagram below shows how a Cloud Miner works. He/she can plug-in his/her wallet address and Amazon Web Services (AWS) API key. Wallets that cannot stake 5,000 Bezops will not receive any mining proceeds.

2 – MINIMAL VIABLE PRODUCT

2.1 Decentralized Order Management

Bezop's Alpha has ended. Its Beta Minimal Viable Product (MVP) is available to the public now.

This world's first Decentralized Order Management (DOM) portal will be linked to the network. The Bezop DOM is a fully developed ecommerce platform that merchants can pull to their web server and use to easily setup an ecommerce store. Users can run a pull request on the Bezop DOM from github and start selling their products and services, and receive Bezops online in a matter of minutes.

2.2 Technologies, Requirements, and Capabilities

Technologies

Bezop DOM is built with HTML5, React JS, Node Js, and MongoDB. These are all open source languages.

Capabilities

Bezop DOM offers a range of solutions that are tailored to serve clients' needs, as described below with some real-world scenarios.

Requirements

Running Bezop DOM requires installation of the following dependencies:

- LAMP / WAMP server
- Mean Stack
- NodeJs

(I) Store Creation

Client 1

Jane is the owner of a small business that sells sports outfits and kits with a price range of USD 10 - 150. She wants to build her own digital store where she can easily transact with her clients online without the frustration of having to pay massive fees for using a centralized portal to execute transactions.

Bezop solution for Client 1

With Bezop DOM, Jane can instantly run a fully decentralized ecommerce portal without the need to access PrestaShop, Shopify, Amazon, or other centralized ecommerce stores that charge hefty transaction fees and/or monthly fees.

Client 2

John is the owner of a medium-sized business that sells electronics with a price range of USD 99 - 1,999. He recently acquired an online store, but finds himself in constant dispute with his merchant service providers. He waits 21 days for credits to clear into his account and prefers not to wait that long to send funds back to his suppliers.

Bezop solution for Client 2

With Bezop DOM, John is not governed by any central body and can process his own transactions by linking the Bezop main address and Bezop tax address into the Bezop DOM online store. His funds will be automatically cleared immediately after he provides proof of delivery, typically within minutes.

(II) Product Addition - limitless by design

Client 3

Jude is the owner of a large supermarket where he sells hundreds of items at prices ranging between USD 99 and USD 1,999. He has an online store but is restricted to displaying only 200 of his products at a time.

Bezop solution for Client 3

Bezop DOM is optimized to allow as many products as Jude desires with a low memory footprint and storage requirements.

(III) Product Categorization

Client 4

Ray is the owner of a large-scale business that sells products by category. He needs a simple solution to start selling online and needs to implement this structure without having to handle the inherent complexity in design or programming himself.

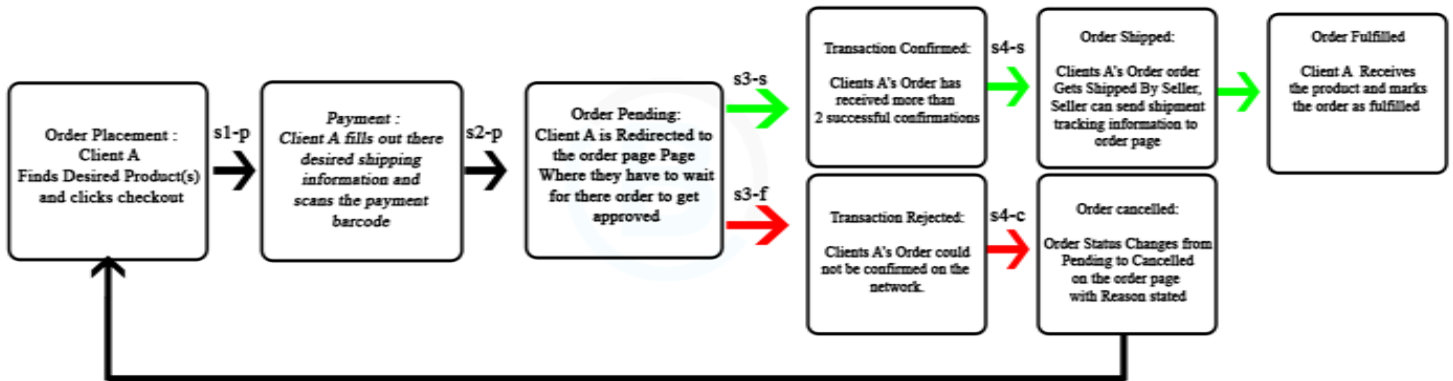

Bezop solution for Client 4

Bezop DOM is optimized to allow Ray to categorize and segment his store into multiple departments which his customers can access through an auto-generated menu. With a centralized version of the system, Ray would need to write a content management plugin and other codes, and re-configure various databases in order to achieve the same effect.

(IV) Order Management

Bezop DOM provides an ideal order management system that displays order status and flags status changes, as described below.

Flags : -p proceed ; -s success ; -f failure ; -c cancelled

(s1-p): stage 1 -proceed

This status message indicates a 1-step procession from order placement. In this stage, the buyer is ready to provide his/her email address and shipping information for delivery.

(s2-p): stage 2 -proceed

This status message indicates a 2-step procession from order placement. In this stage, the buyer has successfully paid for the product/service and is redirected to the order page where he/she must verify the information so that his/her orders can be confirmed on the network.

(s3-s): stage 3 -success

This status message indicates a 2-step procession from order placement and 1-success transition. In this stage, the buyer's transaction has received more than 2 successful confirmations.

(s3-f): stage 4 -failure

This status message indicates a 2-step procession from order placement and 1-failure transition. In this stage, the buyer's order has not received any successful confirmations and, as a result, fails.

(s4-s): stage 4 -success

This status message indicates a 2-step procession from order placement and 2-success transitions. In this stage, the buyer's order has been shipped by the seller.

(s4-c): stage 4 -cancelled

This status message indicates a 2-step procession from order placement and 1-failure transition and order cancellation. In this stage, the transaction has been cancelled because the buyer's order failed. The buyer will be provided a link back to his/her cart. He/she can choose to reorder.

Order Fulfillment

This is the last stage where an agreement is reached between the buyer and the seller indicating that the transaction is complete.

(V) Customer Support Messages

Bezop DOM will allow buyers to exchange messages with sellers after orders have been placed. This will allow both parties to stay in sync.

(VI) Generation of Proof of Tax Chain

A pioneering feature of Bezop's is its ability to collect VAT and segment funds into two addresses - a primary (Main) address and a secondary (Tax) address - when both addresses are entangled. The proof of tax chain makes it possible to generate a table for all valid transactions, with funds split between the Main Address and the Tax Address.

```
Trigger_contract("PoTxM","PoTxV") //Function returns Xm, Xv
XM; XV; I:INT=0; XM:ARRAY=[T1,T2,T3,...,TN] //holds transaction history
XV:ARRAY=[T1,T2,T3,...,TN] //vat history
WHILE I<COUNT(XM){PRINT XM[I]}
WHILE I<COUNT(XV){PRINT XM[I]; PRINT <hr />}
```

(VII) Bezop Wallet Integration

Bezop DOM will allow seamless integration with our merchant wallets, easy receipts, and ultra fast processing of transactions. With the help of the Ethereum blockchain, Bezop will clear transactions in one step with one fee, which results in accepting payments generally up to 5X cheaper and faster for merchants. Merchants will be able to accept payments from Ethereum-based wallets.

3 – CROWD TOKEN PROGRAM DETAILS

3.1 Token program details

The Bezop crowdsale and the corresponding token creation process will be issued by Bezop Blockchain Ltd, a United Kingdom Limited Liability Company. The events will be organized around smart contracts running on Ethereum.

Participants, those who are willing to support the development of the Bezop Project, can support the Project by sending Ether currency (ETH) to an address designated by Bezop. Upon Bezop receiving the ETH ("contributions"), the participants will be immediately rewarded with Bezop Tokens (BEZ) at the rate of 1,929 BEZ per 1 ETH. The BEZ will be sent to the participants' wallets.

Key details of the token program are:

- The acceptable currency during the initial coin offering (ICO) is ETH.
- The creation will be capped ("Soft Cap") upon receipt of contributions equivalent to USD 421,000. This amount is subject to change before the Token Creation event.
- The Token Creation period will last for sixteen (16) days, unless the Soft Cap is reached sooner.

If the Soft Cap is reached before the end of the 16-day period, contributions will be accepted for an additional 120 hours to accommodate those who wish to participate but missed the short window for BEZ creation.

If the Crowdsale campaign does not reach its minimum capital goal of USD 421,000, all funds will be returned automatically to the BEZ holders through the Ethereum smart contracts.

Token Creation has a hard cap of 21,423 ETH. Upon achieving this cap, token creation will stop and no further contributions will be accepted.

Tokens that are not sold during the Crowdsale will be destroyed automatically by the smart contract.

Due to price volatility, values in ETH are not fixed and can be recalculated anytime.

3.1.1 BEZ Creation Ratios

- 1st price batch until the soft cap is reached: **1 ETH = 1,929 BEZ**
- 2nd price batch after the soft cap is reached: **1 ETH = 1,500 BEZ**

The contribution limits for each price batch will be announced.

3.1.2 BEZ Tokens

The Bezop token will be an Ethereum-based token of value. The token is a digital asset, bearing value by itself based on its underlying assets, properties and/or associated rights. Ethereum-based tokens rely on a well-established Ethereum infrastructure, benefiting from several advantages:

- Security and predictability (as opposed to, for example, having to run an independent blockchain network).
- Use of robust and well-supported clients (Ethereum-based tokens can be managed with official Ethereum clients).
- High liquidity (interchangeable with other Ethereum-based tokens or Ether), easier listing on exchanges with infrastructure already in place. Our Ethereum-based token contract complies with the ERC-20 standard. More detailed information about the ERC-20 standard can be obtained from <https://github.com/ethereum/EIPs/issues/20>.

3.1.3 Incentive program

Anyone can participate in Bezop's incentive program by signing up at <https://bitcointalk.org/index.php?topic=2635554>

3.1.4 Budget

All funds raised will go straight into the development and maintenance of Bezop.

55% of the funds raised will go directly into the development and expansion of the Bezop team.

10% of the funds will go towards legal work to ensure Bezop is compliant with all regulatory standards in all countries Bezop operates in.

5% will go into technology improvements such as server and infrastructure upgrades, security (purchasing EV SSL certificates), etc.

10% will go towards marketing Bezop to increase awareness about the platform and attract more users.

10% will be invested into advertising along with training users who wish to start making money online as a Bezop merchant.

10% will be used to buy back Bezops (see Bezop buyback program). No Bezop token will be issued to any Bezop team member.

4 - ROADMAP

MVP PUBLIC RELEASE

1 Bezop's Minimal Viable Product will be Released
First week of december

12th December, 2017

20th December, 2017

TOKEN LAUNCH

2.1

Bezop token sale is scheduled for 3rd week of december and tokens will be released once the ico ends.

20th January, 2017

LISTING ON EXCHANGES

2.2

Bezop tokens will engage exchanges and tokens will be tradable by 20th January

Standard Wallet Release

3 The release of a standard wallet is scheduled 60 days after the token sale

Feb - March, 2018

Decentralize Order Management Release

4

Stable Release Of Bezop DOM. marketing begins July.

June - July, 2018

Major

Merchant Wallet Release

5

Bezop Merchant Wallets and Other Smart Contracts are Finalised. Thousands of merchants can start selling with bezop.

August, 2018

2019

Bezop Network

6

Bezop splits to its own network

Q1

Messier Upgrade (Security Upgrade)

7

Mandatory Security Review And Upgrade is performed

Q3

Andromeda Upgrade (Network Upgrade)

8

General Network Review And Upgrade is Performed

Q4

5 – WHO WE ARE

5.1 Our Mission

The primary objective of Bezop is to provide a viable and scalable ecommerce solution that will incentivize businesses and individual traders to sell goods and services using blockchain technology.

Bezop is a complete solution for running a successful ecommerce business online for new and experienced users. Anyone can sell their products and services and get paid in Bezop without any programming.

Bezop implements a novel Proof-of-Order that lowers the rate of fraud for both merchants and consumers, using elegantly designed contracts powered by the Ethereum blockchain and secured cryptographically. Merchants can collect VAT and accurately manage orders.

The five key components of the Bezop project are:

- i. A DOM portal
- ii. Bezop network
- iii. Proof-of-Order
- iv. Proof-of-Delivery
- v. Bezop Smart Contracts and Promises

Bezop will also revolutionize wallet, private key and transaction encryption using a proprietary Rainbow cipher.

5.2 Bezop Team

Deryck Jones - Chief Technology Officer

Mr. Jones has 20 years of experience in the Fortune 1000, holding dual engineering and marketing roles while overseeing IT operations. He has served as VP of R&D for the software division of a \$3.1 billion Massachusetts Institute of Technology spinout and driven the transformation of a manufacturing business to a \$270 million systems business. He also launched Data-Force, a Salesforce development and sales partner, which delivered services to Sony, Canon, RFS, etc. by developing enterprise software applications and performing enterprise system integrations with SAP, Oracle, and Microsoft SQL Server.

Simon Greenhalgh- Marketing

Simon Greenhalgh has been involved in over 75 software launches since 2008 and has built several ecom brands from the ground up. He specialises in paid traffic and is highly knowledgeable on all the digital advertising platforms. Simon has also amassed a wide range of contacts in the digital marketing industry and has spoken at several events, teaching thousands of people his traffic generating strategies.

Kevin Byrne - eCommerce Expert, Public Relations and Advertising

Kevin holds a Master's Degree in ecommerce and an Honors Degree in Business and Marketing. He is an expert in Facebook advertising and has conquered several platforms such as Shopify. Kevin can generate thousands of sales for a brand new store in a matter of weeks and is ready to transfer his vast ecommerce knowledge, experience, and passion to new merchants.

Camelius “Blaze” Ubah - Lead Engineer

Not only a hardcore developer, Blaze is also a philanthropist and loves giving back to the community. He holds a Bachelor of Science in Computer Science and System Design and has been involved in several revolutionary projects in the software space such as Flexy, an AI project built onto google ML. Working with a strong team of smart contract and blockchain developers, Blaze also leads the development of the Rainbow cipher technology, one of the strongest wallet encryption techniques available today.

Keith Authelet - Advisor

Keith Authelet is the COO/President of Ignition Holdings, Inc., a big data software company that is recognized as a critical analytical tool by the domestic and international intelligence communities. He was the Senior director of IT & bus transformations for 14 years (Lotus Development). Keith has been recognized as a data analytics and cognitive analysis expert. Following his departure from IBM, Keith has consulted all over the world and is frequently sought out for his knowledge in data analytics, big data, business process transformation, and global operations management. Keith holds his degree in Operations Research/Mathematics from the University of Rhode Island.

John McAfee - Advisor

I have become an advisor to bezop.io. I recommended them recently and, as an early investor in their ICO, I want to make sure they succeed in implementation. I love Amazon,.com, but I want everyone to have the ability to be their own Amazon if they want to start an e-business.

Bruce Lavigne - Advisor

Bruce is a TOP international Legal advisor and very well known, He's is an Attorney-at-law aswell as a Certified Public Accountant. Bruce also prides himself as an expert in international Tax . He's a graduate of massachusetts School of Law and Bently University in Public Accountancy.

6 – RESOURCES

6.1 Legal

The Bezop token does not have the legal qualification of a security, since it does not give any rights to dividends or interests. The sale of Bezop tokens is final and non-refundable. Bezop tokens are not shares and do not confer any rights to participate in the general management meetings of Bezop Blockchain Ltd. Bezop tokens cannot have a performance or a particular value outside the Bezop Platform. Bezop tokens shall therefore not be used or purchased for speculative or investment purposes. The purchaser of Bezop tokens is aware that national securities laws, which ensure that investors are sold investments that include all the proper disclosures and are subject to regulatory scrutiny for the investors' protection, are not applicable. Anyone purchasing Bezop tokens expressly acknowledges and represents that she/he has carefully reviewed this white paper and fully understands the risks, costs and benefits associated with the purchase of Bezop.

6.1.1 Knowledge required

The purchaser of Bezop tokens undertakes that she/he understands and has significant experience in the purchase of cryptocurrencies, blockchain systems and services, and that she/he fully understands the risks associated with the crowdsale as well as the mechanism related to the use of cryptocurrencies (incl. storage). Bezop shall not be responsible for any loss of Bezop tokens or situations making it impossible to access Bezop tokens, which may result from any actions or omissions of the user or any person undertaking to acquire Bezop tokens, as well as in case of hacker attacks.

6.1.2 Risks

Acquiring Bezop tokens and storing them involves various risks, in particular the risk that Bezop Blockchain Limited may not be able to launch its operations and develop its blockchain and provide the services promised. Therefore, and prior to acquiring Bezop tokens, any user should carefully consider the risks, costs and benefits of acquiring Bezop tokens in the context of the crowdsale; and, if necessary, obtain any independent advice in this regard. Any interested person who is not in the position to accept or to understand the risks associated with the activity (including the risks related to non-development of the Bezop platform) or any other risks as indicated in the Terms & Conditions of the crowdsale should not acquire Bezop tokens.

6.1.3 Important disclaimer

This white paper shall not and cannot be considered as an invitation to enter into an investment. It does not constitute or relate in any way nor should it be considered as an offering of securities in any jurisdiction. This white paper does not include or contain any information or indication that might be considered as a recommendation or that might be used as a basis for any investment decision. Bezop tokens are just utility tokens which can be used only on the Bezop platform and are not intended to be used as an investment.

The offering of Bezop tokens on a trading platform is done in order to allow the use of the Bezop platform and not for speculative purposes. The offering of Bezop tokens on a trading platform does not change the legal qualification of the tokens, which remain a simple means for the use of the Bezop platform and are not a security.

Bezop Blockchain Ltd is not to be considered as an advisor in any legal, tax or financial matters. Any information in the white paper is provided for general information purposes only and Bezop Blockchain Ltd does not provide any warranty as to the accuracy and completeness of this information.

Bezop Blockchain Ltd is not a financial intermediary according to British law and is not required to obtain any authorization for Anti Money Laundering purposes. Acquiring Bezop tokens shall not grant any right or influence over Bezop Blockchain Ltd organization and/or governance to the purchasers.

Regulatory authorities are carefully scrutinizing businesses and operations associated with cryptocurrencies around the world. In that respect, regulatory measures, investigations or regulatory actions may impact Bezop Blockchain Ltd's business and even limit or prevent it from developing its operations in the future. Any person undertaking to acquire Bezop tokens must be aware of the Bezop Blockchain Ltd business model. The white paper or Terms and Conditions may change or need to be modified because of new regulatory and/or compliance requirements ensuing from applicable laws in any jurisdictions.

In such a case, purchasers and anyone undertaking to acquire Bezop tokens acknowledge and understand that neither Bezop Blockchain Ltd nor any of its affiliates shall be held liable for any direct or indirect loss or damage caused by such changes.

Bezop Blockchain Ltd will do its utmost to launch its operations and develop the Bezop platform. Anyone undertaking to acquire Bezop tokens acknowledges and understands that Bezop Blockchain Ltd does not provide any guarantee that it will manage to achieve it. They acknowledge and understand therefore that Bezop Blockchain Ltd (incl. its bodies and employees) assume no liabilities or responsibilities for any loss or damage that would result from or relate to the incapacity to use Bezop tokens, except in case of intentional misconduct or gross negligence.

6.1.4 Representation and warranties

By participating in the Crowdsale, the purchaser agrees to the above and, in particular, they represent and warrant that they:

- Have carefully read the terms and conditions attached to the white paper, agreed to the full content, and accepted to be legally bound by them;
- Are authorized and have full power to purchase Bezop tokens according to the laws that apply in their jurisdiction of domicile;
- Are neither a U.S. citizen or resident;
- Live in a jurisdiction which allows Bezop Blockchain Ltd. to sell Bezop tokens through a crowdsale without requiring any local authorization;
- Are familiar with all related regulations in the specific jurisdiction in which they are based and that purchasing cryptographic tokens in that jurisdiction is not prohibited, restricted, or subject to additional conditions of any kind;
- Will not use the Crowdsale for any illegal activity, including but not limited to money laundering and the financing of terrorism;
- Have sufficient knowledge of the nature of the cryptographic tokens and have significant experience with, and functional understanding of, the usage and intricacies of dealing with cryptographic tokens and currencies and blockchain-based systems and services;
- Purchase Bezop tokens because they wish to have access to the Bezop platform;
- Are not purchasing Bezop tokens for the purpose of speculative investment or usage.

Bezop: Decentralized Ecommerce Network with Verifiable Proof Of Delivery.

A Technical Analysis On 5 Key Components Of A Secure Decentralized ecommerce Network.

By Bezop Blockchain Ltd

Open Source Project, <https://opensource.org/licenses/MIT>

September 26, 2017

ABSTRACT

The world wide web is experiencing a change, not functional; of design and structure. The inevitable end of centralized proprietary services will be effectively replaced with decentralized and democratized options; elimination of unreliable and human-based trust with immutable and mathematical trust verifiable by computation; a permanent overhaul of location based address with resilient content addresses; inefficient and inflexible primitive(centralized) services will witness less demand as peer-based algorithmic technologies continue to thrive. Bitcoin, Ethereum, and other blockchain networks have proven the utility of decentralized transaction ledgers.

These public ledgers process sophisticated smart contract applications and transact crypto-assets worth tens of billions of dollars. These systems are the first instances of public accessible Open Services, where participants form a decentralized network providing useful services for credit, with no central management or trusted parties.

Decentralized applications are forced to tackle quickly challenges of "legality of purpose," handling fraud and money laundering else strict regulations will emerge if it is believed to "aid or abet breaking of the laws of the land." At the moment, blockchain technology may be widely perceived of as an easy medium for tax evasion because transactions occur secretly and cryptographically, which is the core and fundamental feature. There is no easy way for a business to adopt blockchain and prove they are tax free; hence, not ideal for some businesses. While there are many more critical issues such as scaling, security and stability, the aforementioned pose a direct threat to blockchain's survival.

Bezop is a decentralized peer to peer ecommerce order management and processing system powered by smart contracts, an autonomous buyer-seller protection service and an simple vat collection system all built on a decentralized blockchain network. Bezop aims to provide an open source and complete solution for running a successful ecommerce business online . Merchants can participate by selling products and services on their self-hosted ecommerce stores (the Bezop DOM) and broadcast orders to the network.

The Bezop market runs on a blockchain with a native erc-20 protocol token (also called "Bezop"), which miners earn on the ethereum blockchain by proof of work. Clients spend Bezop in purchasing goods and services on Bezop DOM and other integrated sites offering services and accepting payment in Bezops. Conversely one can earn Bezops by selling goods and services and or simply receiving Bezop via wallet to wallet transfer. In the future, a Bezop network will emerge where miners compete to mine blocks with sizable rewards; however, Bezop mining power will be proportional to active orders on the network. Hence, the usefulness of Bezop's mining will not be limited to maintaining blockchain consensus. This creates a powerful incentive for miners to fulfil as many orders as they can.

The protocol weaves these amassed resources into a self-healing blockchain network that anybody in the world can rely on. The network achieves robustness by implementing very powerful buyer protection techniques through smart contracts. The protocol's order management portal provides adequate security, as orders are encrypted end-to-end at the client, while miners do not have access to decryption keys. Bezop works as an incentive layer on top of blockchain, which computes a proof of order for any transaction. It is especially useful for decentralizing payments, building and running distributed ecommerce portals, and implementing smart contracts.

This work:

(a) Introduces the Bezop Network, gives an overview of the protocol, and walks through several components in detail

(b) Decentralized order management and its properties

(c) Implementation on Ethereum Network & Erc-20 tokens

(d) Introduces the "proof-of-order", which allows proving a transaction with rich details of the purchase as well as verifiable proof of delivery (which is a sufficient proof) the product/service was delivered, vat collection and proof of correctness for chain of transactions

(e) Discusses use cases, connections to other systems, and how to use the protocol. Bezop is a work in progress. Active research is under way, and new versions of this paper will be announced at <https://bezop.io/changes/changelog.pdf> For comments and suggestions, email research@Bezop.io.

1. Introduction

Bezop is a protocol token whose blockchain runs on Proof-of-Work, where blocks are created by miners that are confirming orders (transactions). A **proof of work** is a piece of data which is difficult (costly, time-consuming) to produce but easy for others to verify and which satisfies certain requirements. Producing a proof of work can be a random process with low probability so that a lot of trial and error is required *on average* before a valid proof of work is generated. Bezop uses the Hashcash proof-of-work system.

One application of this idea is using Hashcash as a method to preventing email spam, requiring a proof-of-work on the email's contents (including the To address), on every email. Legitimate emails will be able to do the work to generate the proof easily (not much work is required for a single email), but mass spam emailers will have difficulty generating the required proofs (which would require huge computational resources).

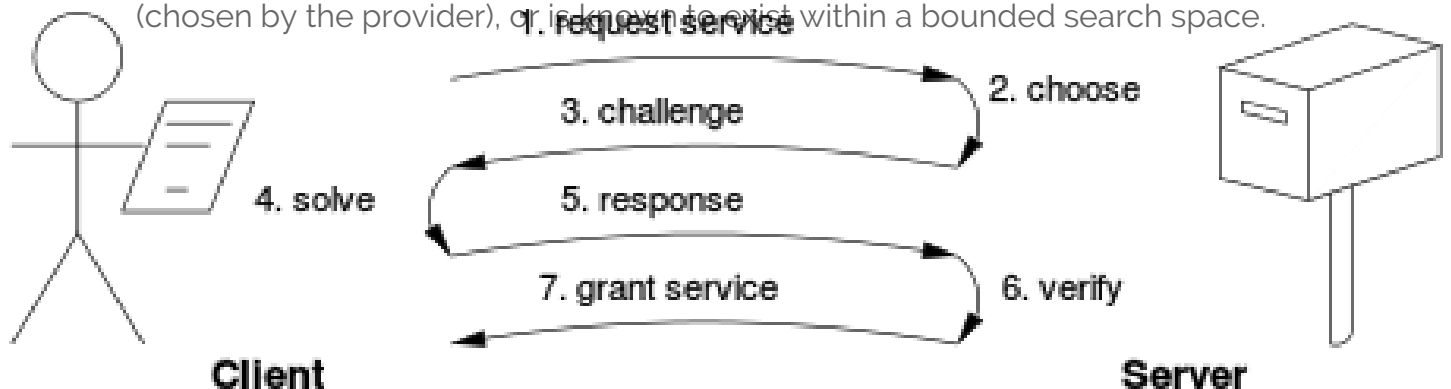

Hashcash proofs of work are used in Bezop for block generation. In order for a block to be accepted by network participants, miners must complete a proof-of-work which covers all of the data in the block. The difficulty of this work is adjusted so as to limit the rate at which new blocks can be generated by the network to one every 10 minutes. Due to the very low probability of successful generation, this makes it unpredictable which worker computer in the network will be able to generate the next block.

For a block to be valid it must hash to a value less than the current target; this means that each block indicates that work has been done generating it. Each block contains the hash of the preceding block, thus each block has a chain of blocks that together contain a large amount of work. Changing a block (which can only be done by making a new block containing the same predecessor) requires regenerating all successors and redoing the work they contain. This protects the block chain from tampering.

The most widely used proof-of-work scheme is based on SHA-256 and was introduced as a part of Bitcoin. Some other hashing algorithms that are used for proof-of-work include Scrypt, Blake-256, CryptoNight, HEFTY1, Quark, SHA-3, scrypt-jane, scrypt-n, and combinations thereof.

There are two classes of proof-of-work protocols.

- **Challenge-response** protocols assume a direct interactive link between the requester (client) and the provider (server). The provider chooses a challenge, say an item in a set with a property, the requester finds the relevant response in the set, which is sent back and checked by the provider. As the challenge is chosen on the spot by the provider, its difficulty can be adapted to its current load. The work on the requester side may be bounded if the challenge-response protocol has a known solution (chosen by the provider), or is known to exist within a bounded search space.

- Solution-verification protocols do not assume such a link: as a result the problem must be self-imposed before a solution is sought by the requester, and the provider must check both the problem choice and the found solution. Most such schemes are unbounded probabilistic iterative procedures such as Hashcash.

Known-solution protocols tend to have slightly lower variance than unbounded probabilistic protocols, because the variance of a rectangular distribution is lower than the variance of a Poisson distribution (with the same mean). A generic technique for reducing variance is to use multiple independent sub-challenges, as the average of multiple samples will have lower variance.

1.1 Elementary Components

The Bezop protocol builds upon four novel components.

- Decentralized Order Management (DOM) : Open Source order management and fulfilment portal
- Bezop Network : A smart contract friendly blockchain network
- Proof of Order :A brief overview on the various proofs,
We present these novel Proofs-of-Order in detail (Section 3) .

a. Proof-of-Tax : - a vat transaction holds data

(i) pointing to the main transaction .

- x must be computed for correctness by taking the hash of $\gamma.\Phi$

Tax Data : { α |obj: val , γ |str: val, δ |float: val, ϵ :bool:val, x|str:val }

α - data , γ - timestamp , γ_1 - timestamp of parent transaction

δ - volume , δ_1 - volume of parent transaction

ϵ - bound (inbound :1 , outbound : 0)

Φ - val($\gamma_1.\delta_1$)

i - tid of original transaction

x - correctness byte [hash($\gamma.\Phi$)]

b. Proof-of-Transaction : Serves a receipt, and shows all information about the product or service purchased.

Transactional Data : { α |obj: val , β |str: val, γ_1 |str: val, δ_1 |float: val, ϵ :bool:val, tid|str: val }

α - data (see page XX)

β - sender's address , γ_1 - timestamp , δ_1 - volume (amount)

ϵ - bound (inbound :1 , outbound : 0) , tid - transaction id

iv) **Proof-of-Delivery** : Proofs that a product or service was delivered.

v) **Bezop Smart Contracts & Promises** : Smart contracts will enable a completely safe and trustless ecommerce solution working flawlessly together on the proof of order protocol and ensuring buyer protection is made available via the blockchain.

Others :

i **Correctness** : **correctness** of an algorithm is asserted when it is said that the algorithm is correct with respect to a specification. *Functional* correctness refers to the input-output behaviour of the algorithm (i.e., for each input it produces the expected output).

A distinction is made between **total correctness**, which additionally requires that the algorithm terminates, and **partial correctness**, which simply requires that *if* an answer is returned it will be correct. Since there is no general solution to the halting problem, a total correctness

assertion may lie much deeper. A termination proof is a type of mathematical proof that plays a critical role in formal verification because total correctness of an algorithm depends on termination.

For example, successively searching through integers 1, 2, 3, ... to see if we can find an example of some phenomenon—say an odd perfect number—it is quite easy to write a partially correct program (using long division by two to check n as perfect or not). But to say this program is totally correct would be to assert something currently not known in number theory.

Proof-of-Work :

Bezop will be based on the same POW system as Ethereum , which will further be upgraded to our full 'proof of order' where miners do not need to spend computation to mine blocks, but instead confirm orders on the network.

1.2 Ethereum Network , ERC20 Token :

Ethereum is a decentralized platform that runs Bezop , using the power of smart contracts provided by the Ethereum network sales of goods and services, common transactions occurs without any possibility of downtime, censorship, fraud or third party interference.

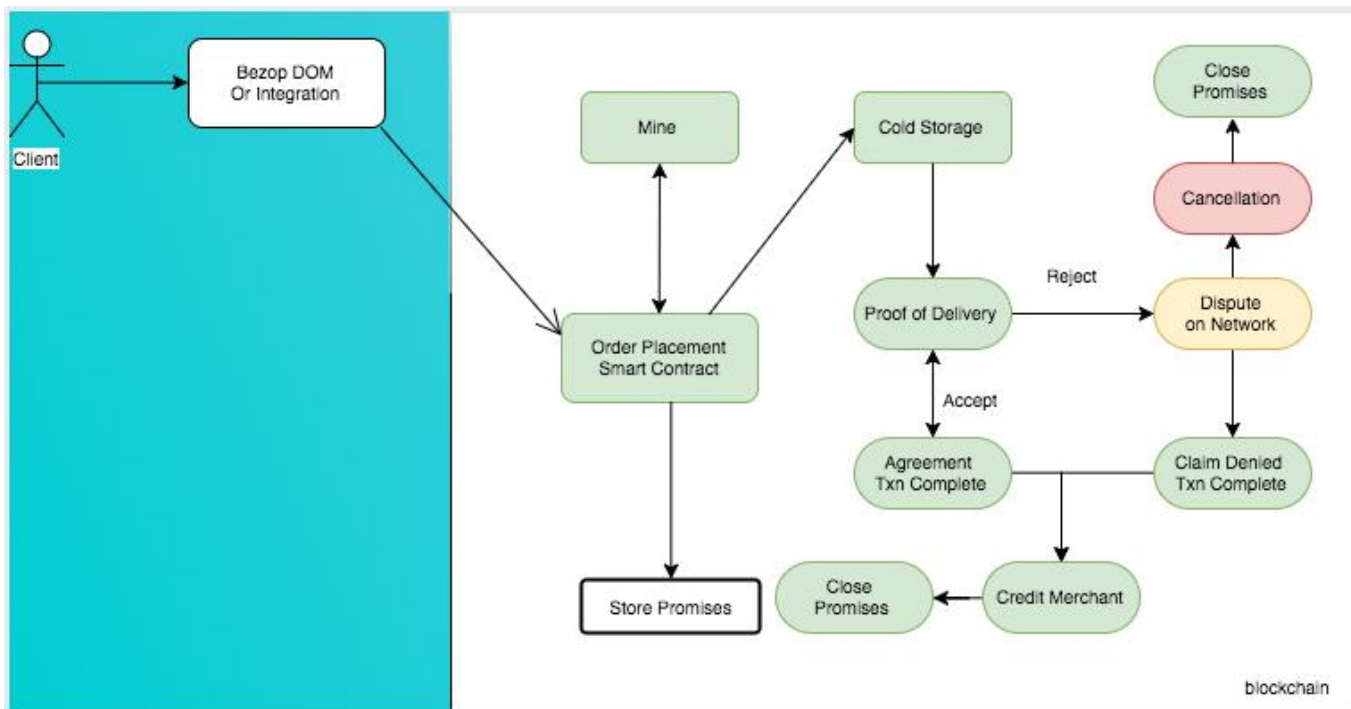

Bezop runs on a custom built blockchain (Ethereum), which is enormously powerful, transparent and a global infrastructure that can move value around and represent the ownership of property. Which will enable us to create the Bezop markets, store registries of transactions, deliveries, order status, tax and also move funds in accordance with instructions given long in the past (like a will or a futures contract) and many other things that have not been invented yet, all without a middleman or counterparty risk.

1.3 Protocol Overview :

- The Bezop protocol is a decentralized ecommerce network built on a blockchain and with a native token. Clients spend tokens in exchange for goods, services, triggering contracts and retrieving tax proof.
 - Miners earn by confirming orders (transactions) and resolving disputes.
 - The Bezop DOM handle orders on the frontend. Store Owners set the price for their product/service and VAT rate and add them to their self operated Bezop platform, Customers send tokens which serve as credit for the goods and service.
 - The markets are operated by the Bezop network which employs Proof-of-Work and Proof-of-Order to guarantee that miners have correctly done work to confirm the order.
 - Finally, miners can participate in the creations of new blocks for the underlying blockchain.
- The

influence of a miner over the next block is proportional to the amount of active orders in the network.

Protocol Overview

1.3 Paper organization

The remainder of this paper is organized as follows. We present our definition of and requirements for a DOM in **Section 2**.

In **Section 3**, we motivate, define, and present our Proof-of-Order, (Proof Of Transaction and Proof-of-Tax), used within Bezop

In **Section 4**, we provide a brief description of Smart Contracts within the Bezop.

We conclude with a discussion of future work in **Section 5**.

2.1 Definition of a Decentralized Order Management

Decentralized Order Management (DOM) is a fully developed ecommerce platform which any interested user can download , host, and run without any central governance or external control.

Users can run a pull request on the Bezop's DOM from github to their self-operated web server . They can start selling their products and services in exchange for Bezop tokens in a matter of minutes.

2.2 Technologies

Bezop DOM is built with HTML5, ReactJS , NodeJs , MongoDB

Which are all open source languages.

2.2 Requirements

Running Bezop DOM requires installation of the following dependencies

- Linux
- Nginx
- NodeJs
- Npm (Node Package Manager)
- MongoDB

2.3 Properties (Described by Real-Life Case Analysis)

(i) Store Creation :

Problem Analysis A - Client 0:

Jane is the owner of a small business where she sells Sports outfit and kits for USD 10 - 150. She wanted to expand and build her own digital store where she can easily transact with her clients online without the frustration of losing massive fees per transaction or monthly fees to access a centralized portal.

Bezop Solutions A :

With Bezop DOM , Jane can instantly run a fully decentralized ecommerce portal. Without the need for PrestaShop , Shopify , Amazon and other centralized ecommerce stores that requires heavy transaction and monthly payments.

Problem Analysis B - Client 1:

John is the owner of a medium scale business and sells electronics for USD 99 - 1999. he recently got an online store but in constant dispute with his merchant service providers. He waits 21 days for credits to clear into his account and prefers not to wait that long to send funds back to his suppliers.

Bezop Solutions B :

With Bezop DOM , John is not governed by any central body and can process their own transaction by linking the Bezop main address and Bezop tax address into Bezop DOM online store. His funds are automatically clears few days after proof of delivery.

Product Addition (Limitless by Design)

Problem Analysis A - Client 2:

Jude is the owner of a Large scale business and Owns a supermarket where the sell hundreds of items of different prices USD 99 - 1999. He has an online store but is limited to only display 200 of his products at a time.

Bezop Solution A :

Bezop DOM is optimized to allow as much products as Jude desires with low memory footprint and storage requirement.

(ii) Product Categorization

Problem Analysis A - Client 3:

Ray is the owner of a Large scale business and where products sold vary by category. He needs a simple solution to start selling online while implementing this structure without handling the inherent complexity in design or programming.

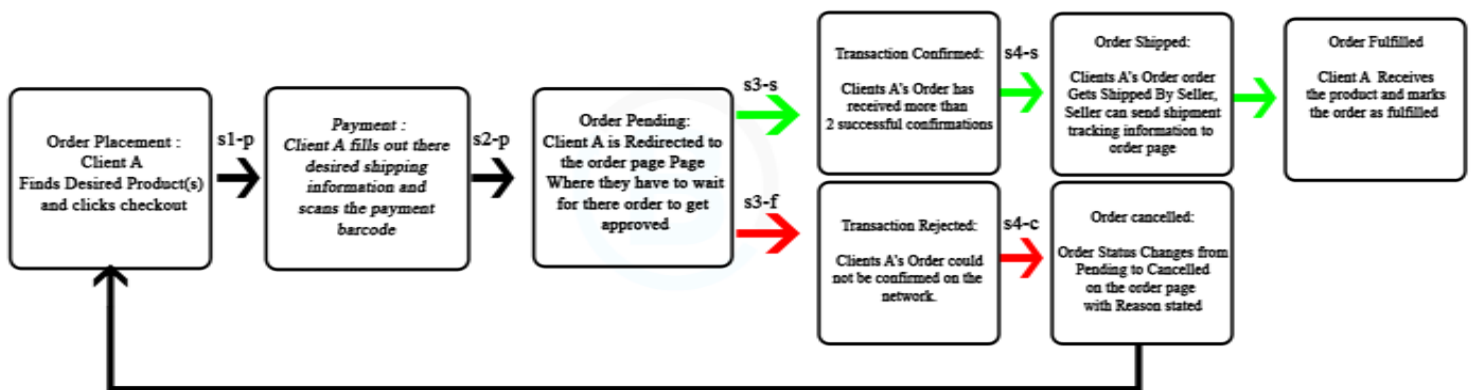

Bezop Solution A :

Bezop DOM is optimized to allow Raymond to categorize and segment his store into multiple departments which users can access through an auto-generated menu. With centralized system, you will need a content management plugin, writing codes, and configuring databases in order to achieve the same effect.

(iii) Order Management

Bezop Decentralized Order Management Portal (DOM) provides an ideal order management system with status codes indicating the order's current stage and flags representing state changes.

Flags : -p proceed ; -s success ; -f failure ; -c cancelled

(s1-p) : stage1 -proceed

This status message indicates a 1-step procession from order placement , in this stage the buyer is now ready to provide their email address and shipping information for delivery of their product. Likewise checkout

(s2-p) : stage2 -proceed

This status message indicates a 2-step processions from order placement, in this stage the buyer has successfully paid for the product/service and are now redirected to the order page where they must for their orders to be confirmed on the network.

(s3-s) : stage3 -success

This status message indicates a 2-step processions from order placement and 1-success transition, in this stage the buyer's transaction has received more than 2 successful confirmations.

(s3-f) : stage4 -failure

This status message indicates a 2-step processions from order placement and 1-failure transition, in this stage the buyer's transaction has not received any successful confirmations and failed .

(s4-s) : stage4 -success

This status message indicates a 2-step processions from order placement and 2-success transitions, in this stage the buyer's order has been shipped by the store owner.

(s4-c) : stage4 -cancelled

This status message indicates a 2-step procession from order placement and 1-failure transition and order cancellation, in this stage the buyer's transaction has now been cancelled because their transaction failed.

The buyer will be provided a link back to their cart. In this scenario, they need to reorder.

Order Fulfilment

This is the last stage and is a positive agreement between the buyer and seller that the transaction is complete.

(iv) Support Messages

Bezop DOM will allow customers to exchange messages with seller after their order has been placed ,

This will allow both parties to stay in sync.

(v) Generation Of Proof Of Tax Chain

A Pioneer feature amongst many is the ability to collect VAT with BEZOP and segment funds into two addresses; a secondary address (Tax address) and a primary (Main Address) - both addresses are entangled. The proof of tax chain makes it possible to generate a comparison table of all valid transaction splits between the Tax Address and the Main Address.

(s1-p) : stage1 -proceed

This status message indicates a 1-step procession from order placement , in this stage the buyer is now ready to provide their email address and shipping information for delivery of their product. Likewise checkout

(s2-p) : stage2 -proceed

This status message indicates a 2-step processions from order placement, in this stage the buyer has successfully paid for the product/service and are now redirected to the order page where they must for their orders to be confirmed on the network.

(s3-s) : stage3 -success

This status message indicates a 2-step processions from order placement and 1-success transition, in this stage the buyer's transaction has received more than 2 successful confirmations.

(s3-f) : stage4 -failure

This status message indicates a 2-step processions from order placement and 1-failure transition, in this stage the buyer's transaction has not received any successful confirmations and failed .

(s4-s) : stage4 -success

This status message indicates a 2-step processions from order placement and 2-success transitions, in this stage the buyer's order has been shipped by the store owner.

(s4-c) : stage4 -cancelled

This status message indicates a 2-step procession from order placement and 1-failure transition and order cancellation, in this stage the buyer's transaction has now been cancelled because their transaction failed.

The buyer will be provided a link back to their cart. In this scenario, they need to reorder.

Order Fulfilment

This is the last stage and is a positive agreement between the buyer and seller that the transaction is complete.

(iv) Support Messages

Bezop DOM will allow customers to exchange messages with seller after their order has been placed ,

This will allow both parties to stay in sync.

(v) Generation Of Proof Of Tax Chain

A Pioneer feature amongst many is the ability to collect VAT with BEZOP and segment funds into two addresses; a secondary address (Tax address) and a primary (Main Address) - both addresses are entangled. The proof of tax chain makes it possible to generate a comparison table of all valid transaction splits between the Tax Address and the Main Address.

```
Trigger_contract("PoTxM","PoTxV") //Function returns Xm,Xv
XM ; XV ; I:INT=0 ; XM:ARRAY=[T1,T2,T3,...,TN] //holds transaction history
XV:ARRAY=[T1,T2,T3,...,TN] //vat history
WHILE I<COUNT(XM){PRINT XM[I]}
WHILE I<COUNT(XV){PRINT XM[I] ; PRINT <hr />}
```

Bezop Wallet Integration

Based on smart contract, Bezop Dom will allow a merchant Bezop Wallet seamless integration, easy receipt and ultra fast transaction processing. With the help of the Ethereum blockchain, we are able to clear transactions into a Bezop wallet with 1 step and 1 fee, which results in accepting payments generally up to 5X cheaper and faster for merchants. Merchants will be able to accept payments from Ethereum-based wallets.

3) Proof Of Order

Allows proving a transaction occurred. In the case of a purchase, it must provide (sufficient proof) the service was delivered, a valid proof of tax (vat collection) and proof of correctness for a single or chain of transactions.

The proof of order adds 'legitimacy' and 'legality of purpose' to every transaction on the Bezop network while remaining decentralized, anonymous and trustless.

Consensus for complete 'Proof of Order'

- Sellers must convince the network that they have delivered the paid products, service or software in good condition; Sellers will generate Proofs-of-Delivery that the blockchain network may verify
- Blockchain Network must store proof of transaction
- Blockchain Network may generate proof of tax

In this section, we motivate, present and outline implementations for the Proof-of-Delivery (PoD) and Proof-of-Transaction (PoT) and Proof-of-Tax (PoT) schemes used in Bezop.

Motivation

Proofs-of-Order schemes such as Proof-of-Delivery (POD) and Proof-of-Transaction (PoT) schemes allow the network (N) to track present state and store transaction data a smart contract protocol with the user.

POD scheme guarantees that an order is delivered.

Attacks

In Bezop, we need stronger guarantees to prevent three types of attacks that malicious sellers could exploit to get paid for products and services they are not providing:

Rogovy attack,
Permanent Eclipse Attack

Rogovy Attack:

This is a kind of attack where several merchants turn rogue and mark large number of orders as delivered while the actual delivery is not as described. In this case a buyer ends up paying for what they cannot use.

Components for Bezop Rogovy Attack

The attacker(s) must own multiple merchant addresses and rapidly trigger Proof-of-Delivery Smart Contract Protocol with the aid of a bot.

The faith of this attack falls on the client's ability to respond in timely fashion.

Permanent Eclipse Attack:

This is a consensus critical vulnerability in the Ethereum peer-to-peer protocol. If the vulnerability is exploited an eclipse attack could cause Denial-of-Service and that can also be used by an adversary to double spend transactions. Due to the low resource requirements of the attack, an attacker with limited capabilities can easily sustain an attack on the whole ethereum network (ultimately Bezop).

Components for Bezop-Ethereum Eclipse Attack

The attack appears to be a vulnerability in the peer-to-peer protocol. However, it was only tested with the geth client.

- Block Propagation

Blocks are propagated in three different ways in the Ethereum network. Firstly, a node B that receives a new block, will directly push the block to \sqrt{n} of its connected peers, where n is the total number of connected peers. Secondly, B will send a NewBlockHashes message to all of its peers, advertising a new block.

When a node A receives an advertisement, it will request the block explicitly after 0.5 seconds from a random peer from which it received a corresponding advertisement (unless A received the block from another peer in the meantime) and then forgets about all other advertisements for that block. This means that if A requests the block from B and B fails to answer, it will not request the block from any other peers. If A misses a block, the third method for block propagation is used, which is the block synchronisation explained below in section 1.3.2.

- **Block Synchronisation**

A node will only synchronise with one other node at a time. A node "A" starts a block synchronisation

in the following cases:

"A" starts a connection to a new peer with higher advertised total difficulty (e.g. after joining or rejoining the network).

"A" node advertising a higher total difficulty than "A" connects to "A".

"A" receives a block with higher total difficulty than the head of its current blockchain and is missing some of the blocks ancestors

- **Attack Details**

The following is a consensus critical flaw in the peer-to-peer protocol. Using this vulnerability, an

attacker B can keep a victim A from receiving a block at height $n + 1$ almost indefinitely. While A may receive later blocks from other peers, it will be stalled at height 'n' since it misses a link in the

blockchain. An attacker B can work as follows:

1. B creates a long blockchain starting from the genesis block. This can be done by decreasing the difficulty for each block, thus shortening the time needed to generate a valid proof-of-work.

Creating the alternative blockchain takes a relatively large amount of precomputation. However, once the alternative blockchain exists, it does not need to be computed again and can be used for multiple attacks.

2. If B's chain is shorter than the valid chain, B forges a block with a high block number and valid proof-of-work, i.e., it creates a block without parent that uses an arbitrary value as parent hash.

3. If the attacker blockchain is shorter than the valid blockchain, B also needs to forge a block with block number `MaxHeaderFetch` below the height of A's blockchain and blocks at heights that will be queried in the binary search but are not contained in B's blockchain.

4. B connects to Node A, advertising a high total difficulty.

5. B sends the block header with the highest block number from his chain (or the block created in step 2) to A in response to the first `GetBlockHeaders` request from A.

6. In response to the second `GetBlockHeaders` request from A, B sends the block from its separate

blockchain corresponding to the block number specified in A's message (or the block forged in step 3).

7. In response to the requests from A's binary search, B responds again with block headers from its own blockchain until the genesis block is reached.

8. A will now request blocks starting from the genesis block. B responds with blocks from its own blockchain, while sending only one block in response for each request. For each request, B can introduce a delay of up to 3 seconds.
9. As long as the attack is in progress, A will not be able to synchronise with any other peers.

Proof of work:

The mechanism behind proof of work was a breakthrough because it simultaneously solved two problems. First, it provided a simple and moderately effective consensus algorithm, allowing nodes in the network to collectively agree on a set of updates to the state of the Bitcoin ledger. Second, it provided a mechanism for allowing free entry into the consensus process, solving the political problem of deciding who gets to influence the consensus, while simultaneously preventing Sybil attacks. It does this by substituting a formal barrier to participation, such as the requirement to be registered as a unique entity on a particular list, with an economic barrier - the weight of a single node in the consensus voting process is directly proportional to the computing power that the node brings. Since then, an alternative approach has been proposed called *proof of stake*, calculating the weight of a node as being proportional to its currency holdings and not its computational resources. The discussion concerning the relative merits of the two approaches is beyond the scope of this paper but it should be noted that both approaches can be used to serve as the backbone of a cryptocurrency.

Bezop Mining

If we had access to a trustworthy centralized service, this system would be trivial to implement; it could be coded exactly as described, using a centralized server's hard drive to keep track of the state. However, with Bitcoin we are trying to build a decentralized currency system, so we will need to combine the state transition system with a consensus system in order to ensure that everyone agrees on the order of transactions. Bitcoin's decentralized consensus process requires nodes in the network to continuously attempt to produce packages of transactions called "blocks". The network is intended to create one block approximately every ten minutes, with each block containing a timestamp, a nonce, a reference to (i.e., hash of) the previous block and a list of all of the transactions that have taken place since the previous block. Over time, this creates a persistent, ever-growing, "blockchain" that continually updates to represent the latest state of the Bitcoin ledger.

The algorithm for checking if a block is valid, expressed in this paradigm, is as follows:

- Check if the previous block referenced by the block exists and is valid.
- Check that the timestamp of the block is greater than that of the previous block and less than 2 hours into the future
- Check that the proof of work on the block is valid
- Let $S[0]$ be the state at the end of the previous block
- Suppose TX is the block's transaction list with "n" transactions. For all, i in $0 \dots n-1$, set $S[i+1] = \text{APPLY}(S[i], \text{TX}[i])$. If any application returns an error, exit and return false
- Return true, and register $S[n]$ as the state at the end of this block

Essentially, each transaction in the block must provide a valid state transition from what was the canonical state before the transaction was executed to some new state. Note that the state is not encoded in the block in any way; it is purely an abstraction to be remembered by the validating node and can only be (securely) computed for any block by starting from the genesis state and sequentially applying every transaction in every block. Additionally, note that the order in which the miner includes transactions into the block matters; if there are two transactions A and B in a block such that B spends a UTXO created by A, then the block will be valid if A comes before B but not otherwise.

The one validity condition present in the above list that is not found in other systems is the requirement for "proof-of-work". The precise condition is that the double-SHA256 hash of every block, treated as a 256-bit number, must be less than a dynamically adjusted target, which as of the time of this writing is approximately 2187. The purpose of this is to make block creation computationally "hard", thereby preventing Sybil attackers from remaking the entire blockchain in their favor. Because SHA256 is designed to be a completely unpredictable pseudorandom function, the only way to create a valid block is simply trial and error, repeatedly incrementing the nonce and seeing if the new hash matches.

For instance, a target of ~2187, the network must make an average of ~269 tries before a valid block is found; in general, the target is recalibrated by the network every 2016 blocks so that on average a new block is produced by some node in the network every ten minutes. In order to compensate miners for this computational work, the miner of every block is entitled to include a transaction giving themselves 12.5 BTC out of nowhere. Additionally, if any transaction has a higher total denomination in its inputs than in its outputs, the difference also goes to the miner as a "transaction fee". Incidentally, this is also the only mechanism by which BTC are issued; the genesis state contained no coins at all.

In order to better understand the purpose of mining, let us examine what happens in the event of a malicious attacker. Since Bitcoin's underlying cryptography is known to be secure, the attacker will target the one part of the Bitcoin system that is not protected by cryptography directly: the order of transactions. The attacker's strategy is simple:

1. Send 100 BTC to a merchant in exchange for some product (preferably a rapid-delivery digital good).
2. Wait for the delivery of the product.
3. Produce another transaction sending the same 100 BTC to himself.
4. Try to convince the network that his transaction to himself was the one that came first.

Once step (1) has taken place, after a few minutes some miner will include the transaction in a block, say block number 270,000. After about one hour, five more blocks will have been added to the chain after that block, with each of those blocks indirectly pointing to the transaction and thus "confirming" it. At this point, the merchant will accept the payment as finalized and deliver the product; since we are assuming this is a digital good, delivery is instant. Now, the attacker creates another transaction sending the 100 BTC to himself. If the attacker simply releases it into the wild, the transaction will not be processed; miners will attempt to run `APPLY(S,TX)` and notice that TX consumes a UTXO which is no longer in the state. So instead, the attacker creates a "fork" of the bitcoin blockchain, starting by mining another version of block 270,000 pointing to the same block 269,999 as a parent but with the new transaction in place of the old one. Because the block data is different, this requires redoing the proof of work for the concerned block. Furthermore, the attacker's new version of block 270,000 has a different hash, so the original blocks 270,001 to 270,005 do not "point" to it; thus, the original chain and the attacker's new chain are completely separate. The rule is that in a fork the longest blockchain is taken to be the truth, and so legitimate miners will work on the 270005 chain while the attacker alone is working on the 270,000 chain. In order for the attacker to make his blockchain the longest, he would need to have more computational power than the rest of the network combined in order to catch up (hence, "51% attack"). Bitcoin blocks depend on the hash of all previous blocks. An attacker with immense computing power can redo the proof of work (PoW) for a considerable amount of blocks and can eventually gain a lot of bitcoins but as described in Satoshi's paper, the reward to mine a valid block is much more than to disrupt the network. But in light of falling mining rewards the same does not hold true.

Proof Of Transaction and Delivery

PoT: A digital 'Proof of transaction' is generated by the Bezop network for any and all sale of goods and services, it is publicly viewable, immutable and preserves anonymity for both parties.

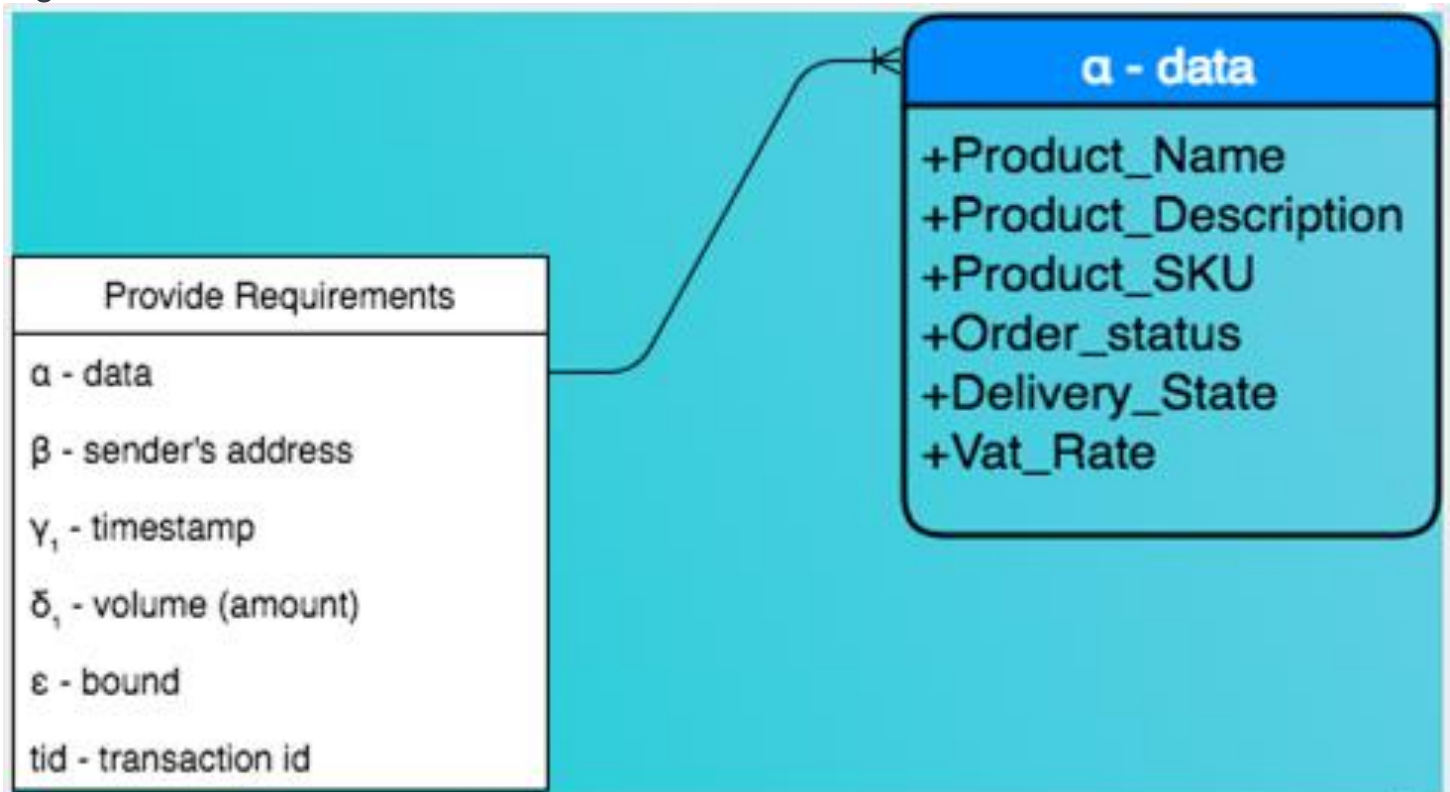

Transactional Data : { α |obj: val , β |str : val, γ_1 |str: val, δ_1 |float : val, ϵ :bool:val, tid|str : val }

α - data , β - sender's address , γ_1 - timestamp , δ_1 - volume (amount)

ϵ - bound (inbound :1 , outbound : 0) , tid - transaction id

α - data is an object containing
Product_Name
Product_Description
Product_SKU
Order_status
Delivery_State
Vat_Rate

Fig Proof Of Transaction (Data Structure)

PoD: Proof of delivery (POD) is a method to establish the fact that the recipient received the contents sent by the sender. When the sender sends multiple physical goods or digital content, there is a possibility of some not reaching the intended recipient.

Proof of delivery becomes very important when legal and financial documents are to be exchanged between two parties. In the United States, DHL, UPS and FedEx as well as the US postal service (USPS) provide proof of delivery. Commercial fleet operators also need to be able to confirm proof of delivery of goods to their customers.

In ecommerce, businesses exchange millions of electronic documents to track delivery information using computer to computer communication techniques like email, FTP and EDI. These documents contain a variety of transaction details, including information regarding purchase orders, invoices, shipping details, product specifications, and price quotes. Electronic documents can exchange new data as well as corrections to previously transmitted messages.

Legal complications can arise if the recipient's company refutes receiving a corrected product specification or a message about a delayed shipment. Both companies could be at loggerheads, each proving/not proving the existence of that particular communication.

Decentralized proof of delivery is similar in function however works in reverse, the shipper/store owner is liable to provide a 'proof of delivery' within 30 days of marking the order as shipped on the network, this can be done through the DOM which is linked to the receiving wallet ; the options are

- a) Providing a link to scanned delivery document
- b) Providing link to proof of delivery screenshot
- c) tracking number of the package

Providing proof of delivery requires a gas fee which Miners will use to confirm the delivery. Once delivery is approved by a miner, the order state is changed to " has been provided", the order is deemed fulfilled, and order_status is updated.

Proof Of Tax

A digital '**Proof of tax**' is generated and stored on the Bezop network for transactions related to sales of goods and services. Bezop's DOM provides a powerful feature which allows users to collect VAT for their products to their secondary wallet address which the network automatically issues to all Bezop account holders. A proof of tax is publicly viewable, immutable and preserves anonymity for both parties.

A tax wallet operates just like a standard wallet with the exception that it is entangled/bonded to the main address using an easily computable hash known as the bond-derivative. The purposes a tax wallet serves are listed below :

- 1) Collecting Value Added Tax (VAT)
- 2) Automatic calculation and generation of tax report

A tax report stored on blockchain is immutable and resistant to loss

Cases

Your Accountant Moves or Closes

Situation: Yesterday, I found myself in quite a predicament when I couldn't get in contact with my old accountant. Turns out his office had closed business just when I needed him to give me a copy tax return to refinance my home. I had been careless and hadn't saved a copy, and had never been really bothered that I hadn't because I always thought my CPA was my backup for maintaining copies of my past tax return and my insurance for that... too bad I was wrong. So what do you do if you find yourself in a similar situation and your tax coach is missing in action?

YOU move and threw away all your papers or just shredded your last tax return copy

Situation: I recently relocated to be closer to my family and my loved ones, but realized that I threw away my last year's tax return copy. I thought for some reason I wouldn't need it, and how my tax preparer is far away and not picking up. My son is going to college and applying for financial aid-I need it to help him get settled here and so I have a piece of mind. How do I get a copy of an old tax return quickly and securely?

You lost your copy of your tax return in a fire or flood

Situation: My family and I just went through a harrowing ordeal of losing our home to a brush fire. Everyone is safe and no one was hurt, but now I have to build my life all over from scratch and I don't even know where to begin. I know I need to get my finances together and to do that I need a copy of my tax returns. I know there's some way to get a copy without having to wait so long for the IRS to send them - I'm homeless and scared I want someone to help me right now! Is there any way I can get a copy of my past tax return and the help that I need?

Your computer crashed with all your copies of tax returns download

Situation: I'm a grad student who is detailed, studious, and organized. But yesterday my computer suddenly crashed with a virus and now I have no access to my tax return copies I filed and saved electronically! I need my financial documents for the bar exam, for my own recordkeeping, and the new lease application that's due tomorrow! Help! Where can I go to ask for help to get a copy of my old tax return at 3AM in the morning?

3) Smart Contracts

3.1 Contracts in Bezop : Smart contracts will enable a completely safe and trustless ecommerce solution on the proof of order protocol and ensuring buyer protection is made available via the ethereum blockchain.

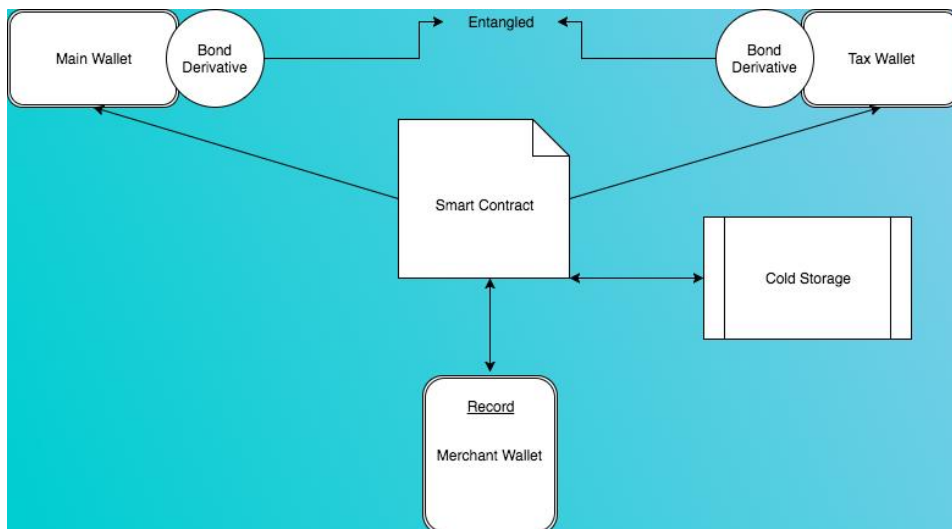

A number of smart contracts, detailed structure and functionality will be defined in this section and finalized with more research. To illustrate the intended functionality, we provide sample workflows illustrating the purchase, cancellation, claim process, and dispute handling on the blockchain.

Merchant Wallet (powered by smart contract):

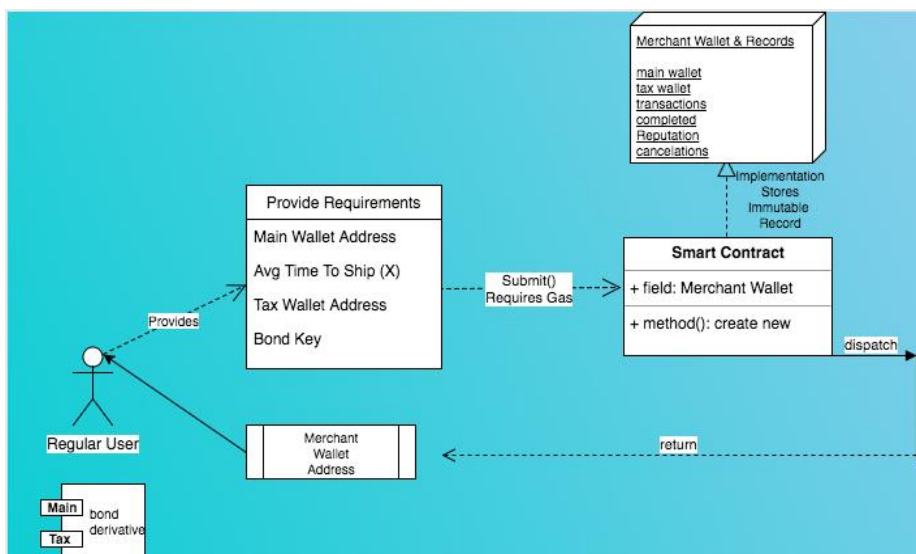

Buyer protection is a critical problem in ecommerce. Bezos DOM (decentralized order management) system is designed to only work with specialized wallets. A standard Bezos wallet is comprised of a "main wallet" and a "tax wallet" entangled using an easily computable hash known as "bond-derivative".

The Merchant wallet is a simple smart contract on the blockchain that does the work of a middle-man (escrow system) and keeps both the client and merchant safe. The contract transfers a client's funds into cold storage. Which is unlockable only after (X) days when proof-of-delivery is provided by the merchant. If a merchant fails to provide PoD, the buyer will have the option to cancel.

Simple Figure shows the merchant/contract wallet design, how the main wallet and tax wallet are linked with a bond-derivative)

Merchant Wallet Creation (smart contract)

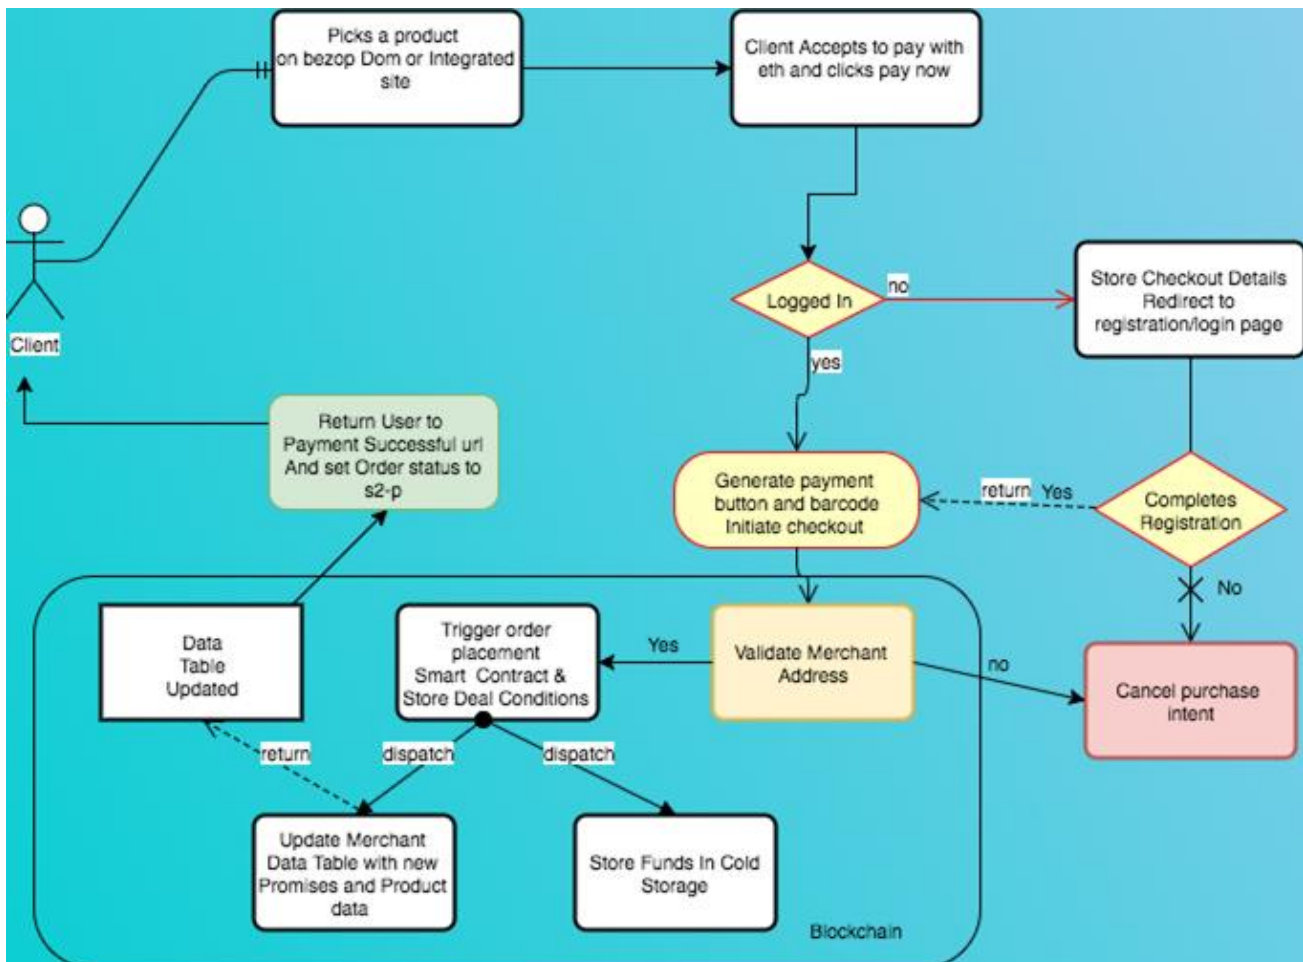

A merchant wallet simulates the behaviour of a normal wallet however it is based on a contract address and operated autonomously.

X signifies the number of days before shipment can be made. This is specified by the merchant while creating their merchant wallet.

Order Placement (Smart Contract)

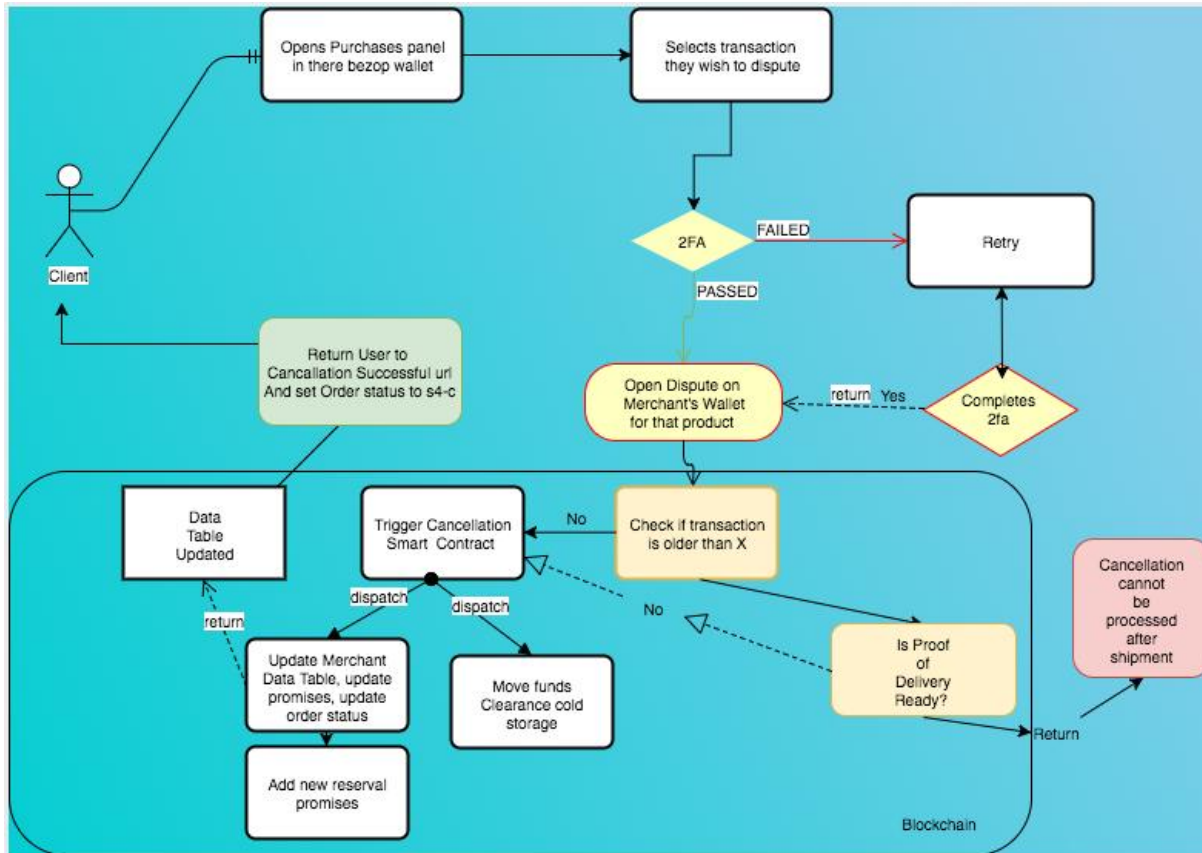

During order placement, tokens are sent to a merchant's wallet address (contract on the Ethereum network), this triggers a smart contract which automatically transfers the funds to a cold secure storage wallet and in place, stores a digital IOU to the registry known as "a Promise record". This promise to credit the main wallet and tax wallet only holds after all conditions have been met for the sale. Some generic conditions are :

- i) X days has passed
- ii) Proof of Delivery is provided
- iii) The transaction was not cancelled
- iv) i,ii,iii are met

Forced Order Cancellation (Smart Contract)

During order cancellation tokens are not sent the client until a safe period has elapsed ,a promise is stored on the merchant's transaction book to return funds to sender after clearance period, all previous promises are voided, the buyer is informed they will receive a refund after clearance days.

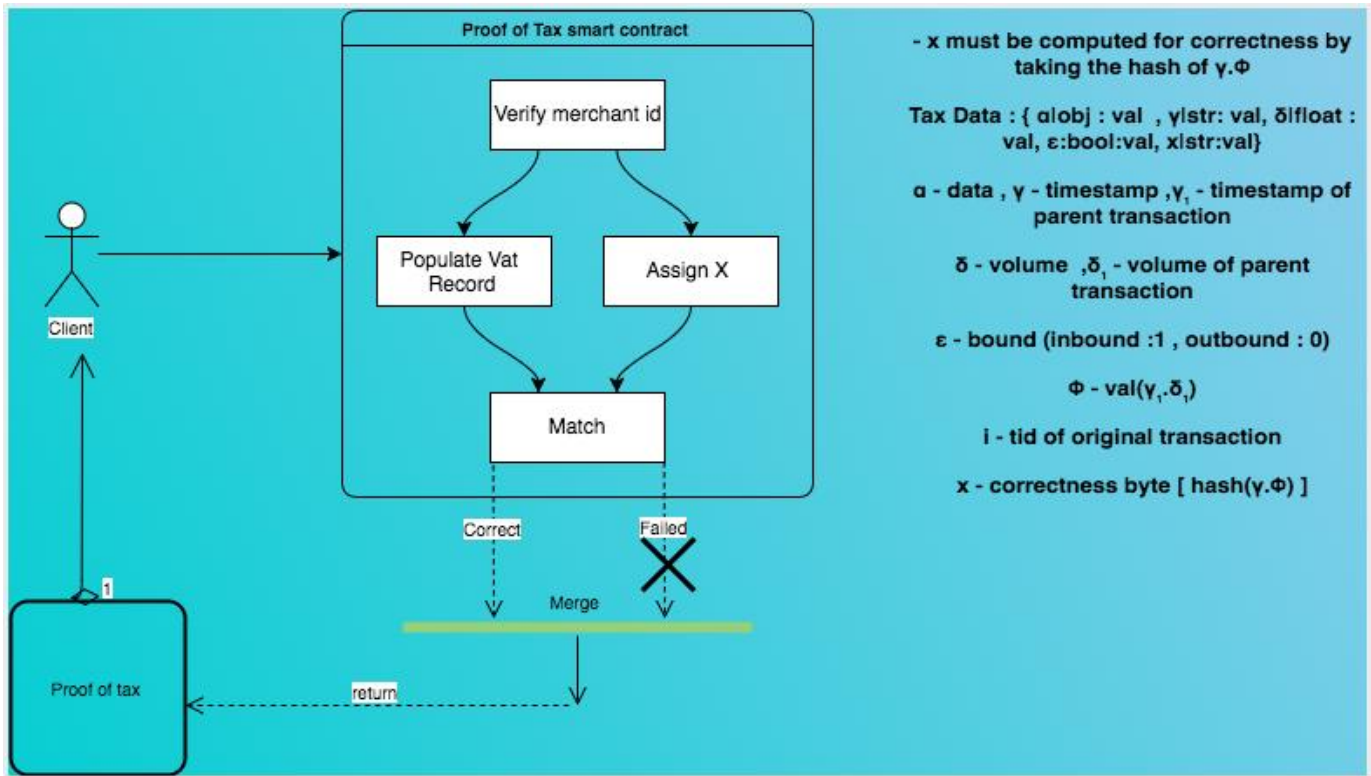

Note : within X days the buyer can cancel the transaction and reverse all payments made if the order is not shipped or they wish not to continue.

Cancelled funds are left in cold storage for 14 days before being restored to the buyer. Gas is required to trigger a cancellation smart contract.

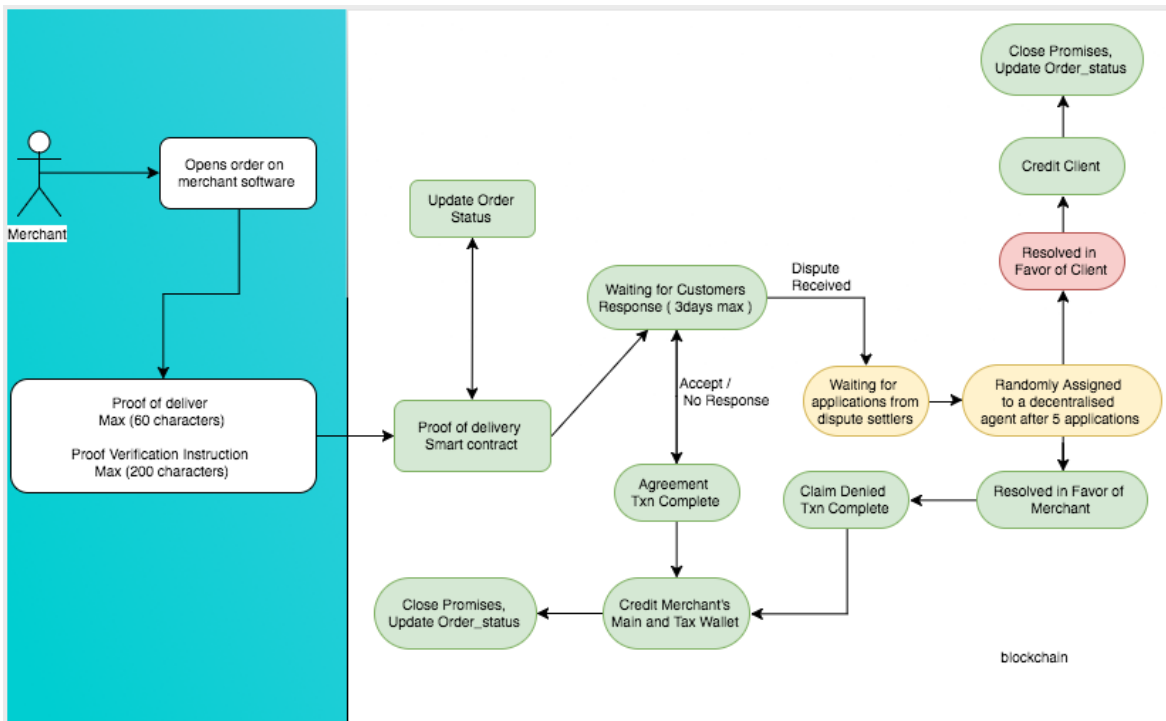

Proof Of Tax (smart contract)

This contract returns all tax data related to a merchant address

Proof Of Delivery (smart contract)

This contract submits proof of delivery for an order to the network.

Once proof of delivery is submitted, The order is marked delivered an extra safety layer allows the client 3 days to dispute the transaction if they have an issue.

A dispute smart contract is different from cancellation contract which is automatic. when a client files an issue with there order after X days have passed and merchant have provided proof of delivery. The network involves 3rd party miners who can earn 0.5% of the transaction by resolving the dispute.

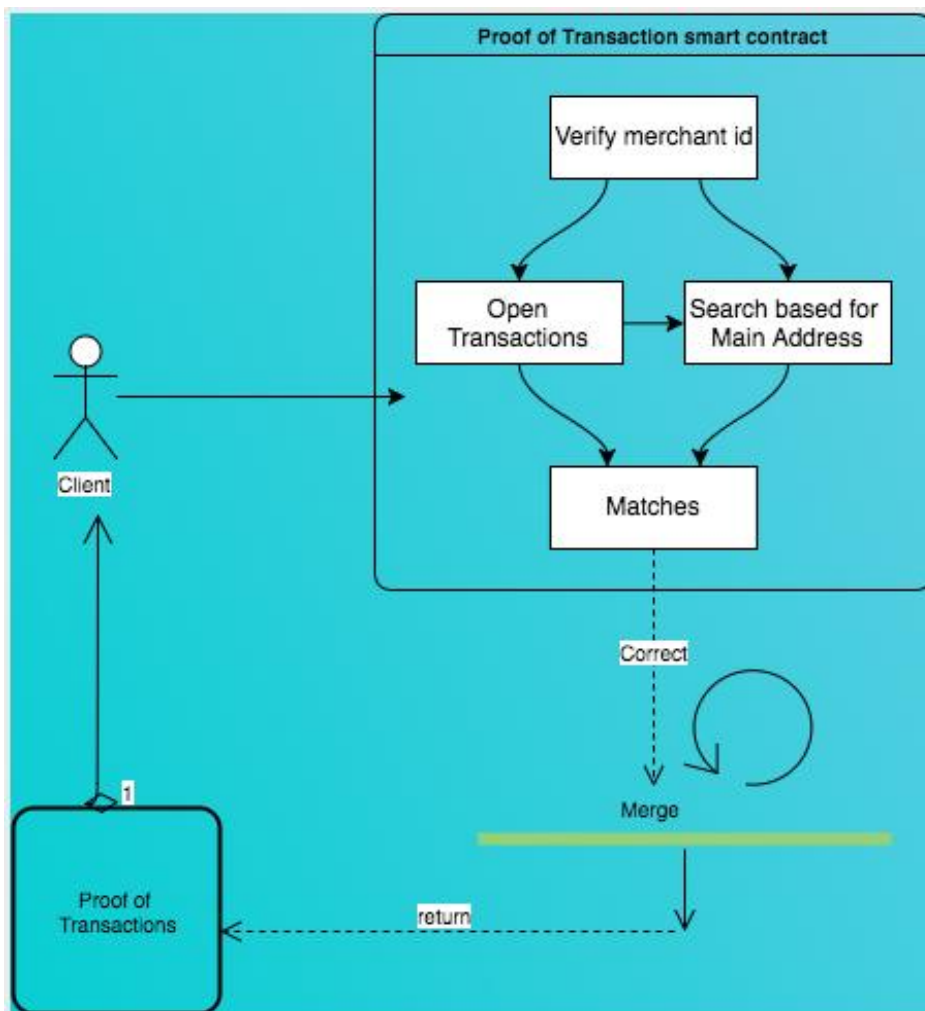

Creating a dispute requires gas.

Decentralized Dispute Agent

dispute agents can verify the proof of delivery provided by the merchant using the instructions and decide to resolve in favor of the client or merchant. Further input is not needed by the merchant or client.

Proof Of Transaction (smart contract)

This smart contract returns transaction data component , For an input merchant address.

4 Future Work

This work presents a clear and cohesive path toward the construction of the Bezop network; however, we also consider this work to be a starting point for future research on decentralized ecommerce systems. In this section we identify and populate three categories of future work. This includes work that has been completed and merely awaits description and publication, open questions for improving the current protocols, and formalization of the protocol.

4.1 On-going Work

Shapeshift Integration

Rainbow wallet

Bezop DOM

Smart Contracts

Bezop Dom Wallet Integration

Product Addition To Network

4.2 Open Questions

Will Bezop feature product rating ?

Yes , future smart contracts will allow users to add products into the network and all purchases must be related to products on the network.

Post purchase , a client will have an extra option to post a rating after proof of delivery is submitted.

Will Bezop split off to its own network ?

Bezop is such a massive concept that a split out of the etheruem network is imminent

Once we have a stable product.

See the whitepaper roadmap - <http://bezop.org/whitepaper.pdf>

Does Bezop host stores for merchants?

At the moment , no .

In the future we may consider that as blockchain becomes more scalable

Merchants will have to find cheap and reliable solutions to host there stores.

Integration with other systems ?

We are at the moment researching this topic, Our Next paper will provide details about This work.

4.3 Proofs and Formal Verification

Because of the clear value of proofs and formal verification, we plan to prove many properties of the Bezop network and develop formally verified protocol specifications in the coming months and years. A few proofs are in progress and more in mind. But it will be hard, long-term work to prove many properties of Bezop (such as scaling, offline).
